**Abstract.** Logics that involve collections (sets, multisets), and cardinality constraints are useful for reasoning about unbounded data structures and concurrent processes. To make such logics more useful in verification this paper extends them with the ability to compute direct and inverse relation and function images. We establish decidability and complexity bounds for the extended logics.

## 1 Introduction and Background

Deductive verification of software often involves proving the validity of formulas in expressive logics. Verification condition generation produces such formulas directly from annotated source code [2, 4], whereas predicate abstraction techniques [3] generate many formulas during fixpoint computation. Abstract interpretation [5] precomputes parameterized transfer functions; the automation of this process [24] also reduces to proving formula validity.

As the starting point of this paper we consider decidable logics whose variables denote collections of objects, corresponding to, for example, dynamically allocated objects in the heap, or concurrent processes. Our logics support standard set algebra operations such as $\cap, \cup$ and complement, as well as the cardinality operator that computes the number of elements in the collection, then imposes linear integer arithmetic constraints on the cardinalities. One such logic is QF-BAPA (quantifier-free Boolean Algebra with Presburger Arithmetic), which was recently proved to belong to NP [15]. The result was subsequently generalized to multisets (bags), in which elements can optionally repeat [21, 22]. The usefulness of collections and cardinality measures on them has been illustrated by a number of examples from software analysis and verification, including not only decision procedures [13, 15, 28] but also static analyses that operate directly on the set abstraction or the cardinality abstraction [10, 12, 20].

---

To make the logics of collection more useful, in this paper we generalize them in a natural direction: we introduce functions and relations and allow computing images and inverse images of sets under these functions and relations. Our primary motivation is that in verification problems, collections such as sets and multisets are often defined by computing an image of a more concrete data structure, often itself a set (see Section 2). The resulting logics are extensions of both the logics with cardinalities, but also of certain previously studied constraints (none of which include symbolic cardinality bounds): certain Tarskian set constraints [9], certain Description Logics [1], and set-valued field constraints [14]. Our techniques are also related to the technique of bridging functions [18]. What distinguishes our result from previous ones is the (often optimal) complexity that we achieve in the presence of sets, multisets, relations, and symbolic cardinality constraints. Our NEXPTIME fragment includes images of $n$-ary relations and is thus not expressible in the two-variable logic with counting [19, 23].

**Contributions.** We summarize the contributions of this paper as follows:

- We describe a new NEXPTIME-complete logic that includes sets, $n$-ary relations, unary functions, and symbolic cardinality constraints.
- We sketch the extension of the logic above with cardinalities of relations and with $n$-ary function symbols; we prove 2-NEXPTIME upper bound for its satisfiability.
- We point to a few simple extensions of the above logic that lead to undecidability.
- We consider an extension of QFBAPA [15] with relation image constraints of a relation between two disjoint sorts of elements results. Using the sort restriction, we show that the sparse model solution phenomenon applies and prove membership in NP (and thus NP-completeness).
- We show NEXPTIME completeness (by reduction to [21]) of a logic that allows computing multisets instead of sets as function images, preserving the multiplicity of elements that occur in the range of the function multiple times. This is a natural definition of the notion of multiset comprehension and arises e.g. when using multisets to abstract the content of a Java-like linked data structures.

## 2 Example

Consider a dynamically allocated data structure (such as a list or a tree) that manipulates a set of linked nodes denoted by the variable nodes. The useful content in the data structure is stored in the data fields of the elements of nodes. The nodes set can be either explicitly manipulated through a library data type or built-in type [6], or it can be verified to correspond to a set of reachable objects using techniques such as [26]. The content of the list, stored in the content specification variable, is then an image of nodes under the function data. We consider two cases of specification in our example: 1) content is a *set*, that is, multiple occurrences of elements are ignored and 2) content is a *multiset*, preserving the counts of occurrences of each element in the data structure.

nodes $\subseteq$ alloc $\wedge$ card tmp $= 1 \wedge$ tmp $\cap$ alloc $= \emptyset \wedge$ data[tmp] $=$ e $\wedge$
content $=$ data[nodes] $\wedge$ nodes1 $=$ nodes $\cup$ tmp $\wedge$ content1 $=$ data[nodes1] $\rightarrow$
        card content1 $\leq$ card content $+ 1$

**Fig. 1.** Verification condition for verifying that by inserting an element into a list, the size of the list does not decrease. The variables occurring in the formula have the following types: nodes, alloc, tmp, e, content, content1 :: Set$\langle$E$\rangle$, data :: E $\rightarrow$ E.

nodes $\subseteq$ alloc $\wedge$ card tmp $= 1 \wedge$ tmp $\cap$ alloc $= \emptyset \wedge$ data[tmp] $=$ e $\wedge$
content $=$ data[nodes] $\wedge$ nodes1 $=$ nodes $\cup$ tmp $\wedge$ content1 $=$ data[nodes1] $\rightarrow$
        card content1 $=$ card content $+ 1$

**Fig. 2.** Verification condition for verifying that by inserting an element into a list, the size of a list increases by one. The variables occurring in the formula have the following types: nodes, alloc, tmp, e :: Set$\langle$E$\rangle$, content, content1 :: Multiset$\langle$E$\rangle$, data :: E $\rightarrow$ E.

The verification condition generated for the case when the image is a set is given in Figure 1. This formula belongs to the language QFBAPA-Rel defined in Section 3 and a decision procedure presented there checks satisfiability of such formulas. It reduces a formula to a (exponentially larger) quantifier-free BAPA formula [15] by introducing Venn regions [25] and cardinality constraints on them, and eliminating the function symbols such as data. The resulting formula can be decided using the NP algorithm in [15], giving NEXPTIME procedure overall.

A more precise abstraction is obtained if content is viewed as a multiset. Figure 2 shows the verification condition for this case. Section 6 describes a decision procedure for an extension of QFBAPA with function symbols where functions can also return a multiset, not only set. The approach also rewrites sets as a disjoint union of Venn regions. It then constrains the cardinality of the multiset obtained through the image to be equal to the cardinality of the original set. This final formula is a formula in the NP-complete logic for reasoning about multisets and cardinality constraints [21, 22].

## 3   QFBAPA-Rel: A Logic of Sets, Cardinalities, Relations, and Unary Functions

This section presents a decision procedure for the language of sets, cardinalities, $n$-ary relations, and unary total functions. The language we consider is denoted QFBAPA-Rel and is defined by the grammar in Figure 3. It naturally extends quantifier-free fragment of BAPA [15] with unary function symbols (denoted by $f, g, \ldots$) and relations of any arity (denoted by $p, q, r, \ldots$ to distinguish them from functions). The expression $f[B]$ denotes the set $\{y \mid \exists x.x \in B \wedge y = f(x)\}$. Cardinality constraints allow us, in particular, to express whether a function is injective on $A$ (by $|f[A]| = |A|$) or surjective onto $A$ ($f[\mathcal{U}] = A$). For a binary relation $r$, the expression $r[A]$ is a relational join expression denoting $\{y \mid \exists x.x \in A \wedge (x, y) \in r\}$. Analogously, $r^{-1}[B]$ denotes $\{x \mid \exists y.y \in B \wedge (x, y) \in$

$r$}. We require functions to be total, whereas relations need not be left-total or right-total. Higher-arity relations have an analogous interpretation with the term $r[B_1, \ldots, B_{i-1}, *, B_{i+1}, \ldots, B_k]$ standing for the set

$$\{x_i \mid \exists x_1 \in B_1, \ldots, x_{i-1} \in B_{i-1}, x_{i+1} \in B_{i+1}, \ldots, x_k \in B_k \land (x_1, \ldots, x_k) \in r\}$$

for a relation $r$ of arity $k$.

The decision problem we are concerned with is the satisfiability problem for QFBAPA-Rel: the question of existence of a finite interpretation $\alpha$ in which formula is true.

An interpretation assigns values to set, integer, function, and relation variables. If $\alpha$ is an interpretation then $\alpha[x := v]$ is an interpration with $\alpha[x := v](x) = v$ and $\alpha[x := v](y) = \alpha(y)$ for $x \neq y$.

\end{aligned}
$$

**Fig. 3.** Syntax of QFBAPA-Rel

### 3.1   Decision Procedure for **QFBAPA-Rel**

Our decision procedure for QFBAPA-Rel satisfiability is a reduction to the satisfiability of quantifier-free Boolean algebra with Presburger arithmetic (QFBAPA). The first step of the reduction is elimination of function inverses and functional and relational composition from the given formula. Because all functions are total, $B = f^{-1}[A]$ is equivalent to $f[B] \subseteq A \land f[B^c] \subseteq A^c$. We allocate a fresh set variable for every functional or relational join application. For example, a formula $f[r[A]] \subseteq h[B \cap C]$ becomes $E \subseteq G \land D = r[A] \land E = f[D] \land F = B \cap C \land G = h[F]$. This separates functional and relational terms from the rest of the formula. Using these transformations we obtain (in polynomial time) a conjunction of a QFBAPA formula $F_{\mathsf{BAPA}}$ and a conjunction of set constraints $F_{\mathsf{IMAGE}}$.

For every function term $f$, formula $F_{\mathsf{IMAGE}}$ contains constraints of the form $A_i = f[B_i]$ where $A_i$ and $B_i$ are set variables. For every relational term $r$ where $r$ is binary, $F_{\mathsf{IMAGE}}$ contains constraints of the form $A_i = r[B_i]$ and $A_i' = r^{-1}[B_i']$ where $A_i, A_i', B_i, B_i'$ are set variables. For a relation $r$ of arity $k$ the formula $F_{\mathsf{IMAGE}}$ contains constraints of the form $A_i^j = r[B_{i1}^j, \ldots, B_{i(j-1)}^j, *, B_{i(j+1)}^j, \ldots, B_k^j]$ for $1 \leq j \leq k$.

4

**Eliminating function applications.** Let $s_1, \ldots, s_m$ be the Boolean algebra terms representing the disjoint Venn regions that are formed by taking intersection $\bigcap_{\alpha_i \in \{0,1\}} b_i^{\alpha_i}$ of all set variables $b_i$ appearing in the entire original formula. For a set $x$, $x^1$ denotes $x$ and $x^0$ denotes $x^c$. We focus on a single function symbol $f$ and its constraints from $F_{\mathsf{IMAGE}}$, We repeat the following algorithm for every function symbol $f$ that appears in $F_{\mathsf{IMAGE}}$.

Let $\bigwedge_i A_i = f[B_i]$ be the constraints for $f$. Each term $B_i$ may be written as a disjoint union of cubes $s_{i_1} \cup s_{i_2} \cup \ldots \cup s_{i_k}$ so that $f[B_i] = \bigcup f[s_{i_j}]$. Because the cubes are disjoint, we can define the values of the function on each cube independently. Introduce set variables $t_j = f[s_j]$. Replace each term $f[B_i]$ with the corresponding union $\bigcup t_{i_j}$ of a subset of cube images:

$$A_i = \bigcup_{s_j \subseteq B_i} t_j \tag{1}$$

After this transformation, the set constraints are reduced to QFBAPA by introducing fresh set variables $t_i$. Moreover, we introduce the following *functional consistency axioms*:

$$\bigwedge |t_i| \leq |s_i| \;\wedge\; (|t_i| = 0 \Leftrightarrow |s_i| = 0) \tag{2}$$

**Theorem 1.** *The projections of the set of solutions (models) for formulas* (1) $\wedge$ (2) *and the formula* $F_{\mathsf{IMAGE}}$ *onto set variables* $A_i, B_i$ *are equal.*

**Proof.** Given a solution of $F_{\mathsf{IMAGE}}$, define the value of $t_j$ as the value of $f[s_j]$. The result is a model satisfying (1) $\wedge$ (2). Conversely, consider a model $\alpha$ of (1) $\wedge$ (2); we construct a model $\alpha'$ that agrees with $\alpha$ on $A_i, B_i$ and has the value $\alpha'(f)$ such that $\alpha'(f[s_j] = t_j)$ holds. For different $s_j$ such definitions are independent. For $\alpha(s_j) = \emptyset$ also $\alpha(s_j) = \emptyset$, so condition $\alpha'(f[s_j] = t_j)$ holds. Otherwise, $0 < |\alpha(t_j)| \leq |\alpha(s_j)|$ by (2). Then there is a surjective function $h : s_j \to t_j$. Pick any such $h$ and define restriction of $\alpha'(f)$ on $s_j$ to be $h$. ∎

**Eliminating binary relations.** Previous procedure does not apply in a straightforward way to relations partly because we do not have a way to express directly inverses for relations that are not total. We instead apply the algorithm in Figure 4 for each relation $r$. The motivation for this algorithm is as follows.

Let $A_i = r[B_i]$ and $A'_i = r^{-1}[B'_i]$ be the constraints from $F_{\mathsf{IMAGE}}$ for $r$. Similarly to the above, let $b_j$ be Venn regions over $B_i$. Introduce fresh set variables $c_j$ that are constrained by $c_j = r[b_j]$. Because relational join commutes with set union, $A_i = r[B_i]$ is equivalent to $A_i = \bigcup_{b_j \subseteq B_i} c_j$. Repeat this procedure for $B'_i$ using $b'_k$ as Venn regions over $B'_i$. We obtain constraints of the form $c_j = r[b_j]$ and $c'_k = r^{-1}[b'_k]$.

Next, introduce new relation variables $r_{jk}$ meant to denote the restriction $\{(x, y) \mid x \in b_j \wedge y \in b'_k \wedge (x, y) \in r\}$ of the relation $r$ to $b_j$ in the domain and $b'_k$ in the codomain. Then $r$ is the disjoint union of $r_{jk}$ over all pairs of $j$ and $k$.

**INPUT:** contrains $\bigwedge_i A_i = r[B_i] \wedge \bigwedge_i A_i' = r^{-1}[B_i']$
**OUTPUT:** an equisatisfiable QFBAPA formula

1. define Boolean algebra terms $b_j$ for Venn regions over $B_i$
2. define Boolean algebra terms $b_k'$ for Venn regions over $B_i'$
3. introduce fresh set variables $L_{jk}, R_{jk}$ for every pair $b_j$ and $b_k'$
4. introduce constraints $L_{jk} \subseteq b_j \wedge R_{jk} \subseteq b_k' \wedge (L_{jk} = \emptyset \iff R_{jk} = \emptyset)$
5. replace each set constraint $A_i = r[B_i]$ with $A_i = \bigcup_{b_j \subseteq B_i} \bigcup_k R_{jk}$
6. replace each set constraint $A_i' = r^{-1}[B_i]$ with $A_i' = \bigcup_{b_k' \subseteq B_i} \bigcup_j L_{jk}$
7. take conjunction of all set constraints from steps 4,5,6

**Fig. 4.** Algorithm for eliminating relations from QFBAPA-Rel

We rewrite the constraints on $c_j, c_k'$ as:

$$\bigwedge_j \left( c_j = \bigcup_k r_{jk}[b_j] \right) \wedge \bigwedge_k \left( c_k' = \bigcup_j r_{jk}^{-1}[b_k'] \right)$$

The behavior of each relation $r_{jk}$ is unrestricted by any other constraints as long as it is a relation from domain $b_j$ to codomain $b_k'$. That means that the relation $r_{jk}$ is determined for our purposes by its domain and range $r_{jk}[b_j]$ and $r_{jk}^{-1}[b_k']$. We introduce two set variables to encode these as $R_{jk}$ and $L_{jk}$, respectively. We rewrite the relation constraints as $c_j = \bigcup_k R_{jk}$ and $c_k' = \bigcup_j L_{jk}$.

The *relational consistency condition* amounts to the following axioms:

$$\bigwedge_{j,k} L_{jk} \subseteq b_j \wedge R_{jk} \subseteq b_k' \wedge (L_{jk} = \emptyset \iff R_{jk} = \emptyset)$$

Because both $j$ and $k$ range over singly exponentially many variables, there are singly exponentially many fresh variables and constraints introduced.

**Theorem 2.** *The algorithm in Figure 4 produces a QFBAPA formula of singly exponential size with the same set of solutions for $A_i, B_i, A_i', B_i'$.*

**Proof.** Because we only made sound syntactic transformations and introduced variables defined by existing terms, it suffices to show that a model of the generated QFBAPA formula extends to a model of the original formula. Assume we are given an interpretation of the QFBAPA formula, that is values of $L_{jk}$ and $R_{jk}$ and the set variables from the original formula $A_i, B_i, A_i', B_i'$. Relation consistency axioms allow us to define total relations $r_{jk}$ by mapping every element from $L_{jk}$ to every element from $R_{jk}$. An interpretation of $r$ is then the union of all these pairwise non-intersecting relations $r_{jk}$. To see that we satisfied the set constraints, consider, for example, constraint $A_i = r[B_i]$:

$$r[B_i] = \bigcup_{b_j \subseteq B_i} r[b_j] = \bigcup_{b_j \subseteq B_i} \bigcup_{j',k} r_{j'k}[b_j] = \bigcup_{b_j \subseteq B_i} \bigcup_k r_{jk}[b_j] =$$
$$= \bigcup_{b_j \subseteq B_i} \bigcup_k r_{jk}[L_{jk}] = \bigcup_{b_j \subseteq B_i} \bigcup_k R_{jk} = A_i \quad \blacksquare$$

**Eliminating higher-arity relations.** The algorithm for binary relations extends naturally to higher-arity relations. We sketch the construction in this section. We focus on a single $k$-arity relation $r$ with set constraints $A_i^j = r[B_{i1}^j, \ldots, B_{i(j-1)}^j, *, B_{i(j+1)}^j, \ldots, B_k^j]$ for $j = 1, \ldots, k$. Similar to above, we introduce Venn regions $b_l^j$ over $j$-th coordinate set variables $B_{ij}$. For a $k$-tuple of Venn regions $\mathbf{v} = (b_{l_1}^1, b_{l_2}^2, \ldots, b_{l_k}^k)$, we consider the restriction $r_\mathbf{v}$ of the relation $r$ to $b_{l_j}^j$ on every coordinate.

Observe that every set constraint can be replaced with a union of application of the relations $r_\mathbf{v}$ to tuples of Venn regions. The key idea is that each such application is uniquely defined by projections of $r_\mathbf{v}$ onto every coordinate. That is we introduce $k$ set variables $\{P_\mathbf{v}^i\}_{i=1,\ldots,k}$ for every relation $r_\mathbf{v}$ such that:

$$\bigwedge_{j=1,\ldots,k} P_\mathbf{v}^j \subseteq b_{i_j}^j \wedge \left( \bigwedge_{j=1,\ldots,k} |P_\mathbf{v}^j| = 0 \vee \bigwedge_{j=1,\ldots,k} |P_\mathbf{v}^j| > 0 \right)$$

Any model to this condition gives rise to a well-defined relation $r_\mathbf{v}$ equal to the Cartesian product of the sets $P_\mathbf{v}^1 \times \ldots \times P_\mathbf{v}^k$ (or empty if any of them is empty). This way we can reconstruct the original relation $r$ from the pairwise disjoint interpretations of relations $r_\mathbf{v}$.

For instance, the following formula represents a set constraint above (after dropping $j$ super-script):

$$A_i = r[B_{i1}, \ldots, B_{i(j-1)}, *, B_{i(j+1)}, \ldots, B_k] = \bigcup_{\text{cube} b_l \subseteq B_{il}} r[b_1, \ldots, b_{j-1}, *, b_{j+1}, \ldots, b_k]$$

$$= \bigcup_{b_l \subseteq B_{il}, l \neq j, \mathbf{v} = (b_l)} r_\mathbf{v}[b_1, \ldots, b_{j-1}, *, b_{j+1}, \ldots, b_k] = \bigcup_{b_l \subseteq B_{il}, l \neq j, \mathbf{v} = (b_l)} P_\mathbf{v}^j$$

The total number of fresh set variables and the size of the resulting formula are still singly exponential in the size of the formula, since we consider Venn regions for each coordinate and take $k$-tuples of these regions for $k$ linear in size.

## 3.2 Complexity of **QFBAPA-Rel**

Combining results of the previous sections, we obtain a reduction from QFBAPA-Rel to QFBAPA. This reduction produces a formula of a singly exponential size by introducing set variables for Venn regions over set variables in the original formula for each function and relation. Because QFBAPA is known to be NP-complete [15], we conclude that **QFBAPA-Rel** is in NEXPTIME. Moreover, we obtain EXPTIME *BAPA reduction* from **QFBAPA-Rel** to QFBAPA [27], which means that the method can be used to combine **QFBAPA-Rel** with other logics, such as the Weak Monadic Second-Order Logic over Trees.

**Theorem 3.** *QFBAPA-Rel is NEXPTIME-complete, even with no relation symbols and with only one unary function symbol.*

**Proof.** The algorithm above established the NEXPTIME upper bound, we next prove the matching lower bound. In [9], NEXPTIME lower bound for Tarskian set constraints with constants and binary functions is shown by reduction of a fragment of first order logic. We adapt this proof to QFBAPA-Rel. The proof relies on the result [16] that acceptance of nondeterministic exponential-time bounded Turing machines can be reduced to satisfiability of formulas of the form $\exists z.F_1 \wedge \forall y \exists x.F_2 \wedge \forall y_1 \forall y_2.F_3$ where $F_1$, $F_2$, and $F_3$ have no quantifiers and are monadic (have only unary predicates). Given a formula of this from, we construct an equisatisfiable QFBAPA-Rel formula as a set of constraints, as follows. We identify monadic predicate symbols with set variables, using the same symbols for both. After Skolemizing the formula by introducing a constant symbol $a$ and a monadic function symbol $f$, and putting $F_1$, $F_2$, and $F_3$ into the conjunctive normal form, there are three types of clauses (as remarked already in [9]); we describe our encoding of each of these clauses.

1. monadic formulas over the constant symbol $a$ (obtained from $\exists z.F_1$)
   We transform the conjunction of all such formula into a set constraint as follows. For each monadic predicate $P$ replace $P(a)$ with $P$, replace $\vee$ with $\cup$, replace $\neg$ with $\_^c$, and $\wedge$ with $\cap$. Let the result of this replacement be a set algebra expression $S$; then generate the QFBAPA-Rel formula $S \neq \emptyset$.
2. clauses of the form:

$$\forall x.P_1(x) \vee P_2(x) \vee \ldots \vee P_m(x) \vee Q_1(f(x)) \vee Q_2(f(x)) \vee \ldots \vee Q_n(f(x))$$

   For each such clause, we generate a constraint:

$$f\left(P_1^c \cap P_2^c \cap \ldots \cap P_m^c\right) \subseteq Q_1 \cup Q_2 \cup \ldots \cup Q_n$$

3. clauses of the form:

$$\forall y_1 \forall y_2.\ P_1(y_1) \vee P_2(y_1) \vee \ldots \vee P_m(y_1) \vee Q_1(y_2) \vee Q_2(y_2) \vee \ldots \vee Q_n(y_2)$$

   For each such clause we generate the QFBAPA-Rel formula:

$$(P_1 \cup P_2 \cup \ldots \cup P_m = \mathcal{U}) \ \vee \ (Q_1 \cup Q_2 \cup \ldots \cup Q_n = \mathcal{U})$$

   (This last constraint differs from the one in [9] and does not require any binary function symbols).

The resulting QFBAPA-Rel formula is equisatisfiable with the original formula, so NEXPTIME lower bound follows from [16]. ∎

### 3.3   Decidable Extensions: n-ary Functions, Relation Cardinalities

We have presented QFBAPA-Rel, as a logic with monadic functions and arbitrary relations and shown it to be NEXPTIME-complete. We next sketch how to extend the decidability to include also the functions of higher arity. Generalizing the method for unary functions, we have for e.g. a binary function $f[p_1 \cup p_2, q_1 \cup$

$q_2] = f[p_1, q_1] \cup f[p_1, q_2] \cup f[p_2, q_1] \cup f[p_2, q_2]$. We apply such reasoning to all Venn regions. This creates a singly exponential blowup in formula size. Given Venn regions $p, q$ and image $f[p, q]$, let their cardinalities be $k_p, k_q, k_{fpq}$, respectively. Then a necessary condition for a function to be definable on $p \times q$ is $k_{fpq} \le k_p k_q$, which is a non-linear constraint. In general, the satisfiability of QFBAPA-Rel with $n$-ary function symbols reduces to the satisfiability of a conjunction of 1) such non-linear constraints $x \le y_1 \dots y_n$ and 2) linear integer constraints. Such conjunctions are called *prequadratic* in [9] and their satisfiability is shown to be in NEXPTIME. (The quadratic as opposed to higher-degree monomials on right-hand side suffice because replacing $x \le y_1 y_2 \dots y_n$ with $x \le y_1 z_1 \land z_1 \le y_2 \dots y_n$ preserves the projection of solution set onto $x, y_1, \dots, y_n$.) The generated prequadratic formula is singly exponential, which gives an upper bound of 2-NEXPTIME for QFBAPA-Rel extended with functions of arbitrary arity.

A similar construction works for an extension of QFBAPA-Rel with the cardinality operator applied to relations (computing the number of related pairs of elements). In the notation of Section 3.1, we add the prequadratic constraints $|r_{jk}| \le |L_{jk}| \ |R_{jk}|$ as well as the appropriate linear constraints.

### 3.4 Undecidable Extensions: Injective Binary Functions, Quantifiers

**Injective binary functions.** If in addition to introducing binary function symbols we allow stating that they are injective, then instead of prequadratic constraints of the previous section we obtain constraints of the form $x = yz$. Indeed, $|f[p, q]| = |p| \ |q|$ for an injective function $f$. Together with linear constraints, these constraints can express arbitrary Diophantine equations (polynomial integer equations). The satisfiability in such language is undecidable [17] (Hilbert's 10th problem), and thus adding an injective function symbol to QFBAPA gives an undecidable logic.

**Relation cardinality with Cartesian product.** We noted that decidability is preserved if we allow computing the cardinality of a relation. However, if we can additionally constrain a relation to be full Cartesian product of two sets, then we again obtain the constraint $|p \times q| = |p| \ |q|$, and the undecidability by [17].

**Quantification.** Note that BAPA with arbitrary set and integer quantifiers is decidable [8,13]. On the other hand, the logic that allows quantification over sets and one function symbols is also decidable [11, Theorem 8.3]. However, a BAPA extension that allows quantified formulas with unary function symbol images is undecidable. Indeed, define a function $f$ mapping $A$ onto $B$ where each inverse image has $k$ elements: $B = f[A] \land \forall e.\ e \subseteq B \land |e| = 1 \Rightarrow |f^{-1}[e]| = k$. Then $|B| = k|A|$ and the set of values $(|B|, k, |A|)$ contains precisely the solutions $(x, y, z)$ of the equation $x = yz$. Recall that $f^{-1}[e] = u$ is expressible by $f[u] \subseteq e \land f[u^c] \subseteq e^c$, so either direct or inverse function image can be used, or a relation restricted to be functional using a quantified formula, in each case resulting in undecidability by [17].

## 4 NP-Complete Two-Sorted **QFBAPA-Rel** Fragment

In this section we identify a fragment of the QFBAPA-Rel logic in Figure 3. Remarkably, this fragment has NP instead of NEXPTIME complexity for the satisfiability problem. Figure 5 shows the syntax of this fragment, QFBAPA-R2, which is an extension of QFBAPA with relation image of one two-sorted binary relation symbol. Compared to full QFBAPA-Rel, there are no function symbols, no inverse images, and there is only one relation symbol, denoted $r$, which is binary. Moreover, each set contains only elements of sort $\mathcal{A}$, or only elements of a disjoint sort $\mathcal{B}$. There are two disjoint universal sets $\mathcal{U}_\mathcal{A}$ and $\mathcal{U}_\mathcal{B}$ for the corresponding sorts. The boolean operators $\cup, \cap$ and complement apply only to sets of the same sort. We require that the relation $r$ relate sort $\mathcal{A}$ to sort $\mathcal{B}$, that is, the semantic condition $r \subseteq \mathcal{U}_\mathcal{A} \times \mathcal{U}_\mathcal{B}$ holds. An example formula in this fragment is $x = y \rightarrow |r[x]| = |r[y]|$. In this formula $x, y$ have sort $\mathcal{A}$ and the expressions $r[x]$ and $r[y]$ have sort $\mathcal{B}$.

$$

**Fig. 5.** Syntax of QFBAPA-R2

**Normal form.** Consider an arbitrary QFBAPA-R2 formula $F$. By introducing fresh variables for sets and integers (similarly as in [15]), we can rewrite the formula in (with only linear increase in size) in the form

$$ F_C \wedge F_B \wedge F_A \wedge P \tag{3} $$

where:

- $F_C$ is $\bigwedge_{i=1}^n B_i = r[A_i]$ and this is the only part of formula containing $r$;
- $F_B$ is of form $\bigwedge_i L_i$ where each $L_i$ is of the form $|b| = k$ for some integer variable $k$ and some set algebra expression $b$ of sort $\mathcal{B}$ (it is thus a QFBAPA formula);
- $F_A$ is analogously of form $\bigwedge_i L_i$ where each $L_i$ is of the form $|a| = k$ for some integer variable $k$ and some set algebra expression $a$ of sort $\mathcal{A}$ (it is thus also a QFBAPA formula);
- $P$ is a quantifier-free Presburger arithmetic formula.

In the sequel we assume that QFBAPA-R2 formulas are in normal form.

**Lemma 4 (Models Modulo Venn Regions).** *Let $p$ be a Venn region over sets $A_i$ and $q$ a Venn region over sets $B_i$. If $\alpha$ is a model of the QFBAPA-R2 formula $F$ and $\alpha(r) \cap (\alpha(p) \times \alpha(q)) \neq \emptyset$, then $\alpha'$ given as $\alpha[r := w]$ is also a model of the formula $F$ where $w = \alpha(r) \cup (\alpha(p) \times \alpha(q))$.*

**Proof.** Relation $r$ occurs only in $F_C$, so it suffices to check that $F_C$ remains true in the new model. Consider an arbitrary index $i$. Because $p$ is a Venn region, either $p \cap A_i = \emptyset$ or $p \subseteq A_i$. In first case $r[A_i]$ does not change and $r[A_i] = B_i$ remains true. Suppose therefore $p \subseteq A_i$. By assumption $\alpha(r) \cap (\alpha(p) \times \alpha(q)) \neq \emptyset$, let $a \in \alpha(p)$ and $b \in \alpha(q)$ such that $(a, b) \in \alpha(r)$. Because $\alpha(r[A_i] = B_i)$ holds, $b \in \alpha(B_i)$, and as $b \in \alpha(q)$, the Venn region $q$ is of the form $s \cap B_i$, so $q \subseteq B_i$ in all models. Thus, omitting the applications of $\alpha$ symbol for brevity,

$$\alpha'(r[A_i]) = (r \cup (p \times q))[A_i] = r[A_i] \cup (p \times q)[A_i] = B_i \cup q = B_i = \alpha'(B_i)$$

and the conjunct continues to hold. ∎

By repeated application of the lemma it follows that it suffices to consider *completed models* $\alpha$, in which $\alpha(r)$ is a union of products of Venn regions, and is thus given by a bipartite graph, denoted $E$, between Venn regions of sort $\mathcal{A}$ and Venn regions of sort $\mathcal{B}$.

**Sparse models.** We are interested in the finite satisfiability problem for QFBAPA-R2 formulas. We show that this problem is in NP. This result is a strict a generalization of the proof that QFBAPA is in NP [15] and similarly proceeds by proving a *sparse model property*: if the formula is satisfiable, it has a model in which only polynomially many Venn regions are non-empty. By Lemma 4, models with sparse Venn regions can also be assumed to have polynomial representations that have polynomial sized bipartite graphs $E$. By *polynomial* in this section we mean polynomial in the size of formula $F$, where integer constants are denoted in binary.

The following theorem builds on the sparse model property for QFBAPA [15]. QFBAPA models can be represented by introducing an integer variable for each Venn region, and the sparse model property for QFBAPA relies on the integer analogue of Carathéodory theorem [7].

**Theorem 5.** *If a QFBAPA-R2 formula $F$ has a model, then it has a sparse model.*

**Proof.** Let $\alpha$ be a completed model of formula $F$ in form (3). Using $\alpha$ we simplify $F_C$ as follows. For all sets $A_i$ where $\alpha(A_i) = \emptyset$, replace $A_i$ and $B_i$ with $\emptyset$ and remove such $A_i$ and $B_i$ from consideration. Let $K$ be the number of sets $A_i$ remaining. For the remaining sets $A_i$, introduce constraint $|A_i| = k_i'$ into $F_A$ and constraint $k_i' > 0$ into $P$.

Next, apply the sparse model construction of QFBAPA to $F_B$ part, as follows. Consider the result of replacing in $F_B$ each integer variable $k$ with the constant $\alpha(k)$. By [15], consider a sparse solution for the resulting QFBAPA formula that does not introduce any new non-empty Venn regions. That is, consider the

Presburger arithmetic formula generated by those Venn regions $q$ over sets $B_i$ for which $\alpha(q) \neq \emptyset$, eliminating the variables corresponding to Venn regions $q$ with $\alpha(q) = \emptyset$. The sparse solution of such Presburger arithmetic formula [7,15] yields a polynomial subset of non-empty Venn regions over $B_i$ for which the integer values of $|b|$ expressions in $F_B$ remain the same. We therefore obtain a set of cubes $C_B = \{q_1, \ldots, q_N\}$ and a model $\alpha_1$ such that 1) $\alpha_1(q) \neq \emptyset$ iff $q \in C_B$, 2) $\alpha_1(F_B \wedge P)$, and 2) variables other than $B_i$ have same values in $\alpha_1$ and $\alpha$.

Next, pick a set $C_{A0}$ of cubes over $A_i$ related to the chosen sparse set of cubes $C_B$. Let $1 \leq j \leq N$. Let $i$ be any index such that $q_j \subseteq B_i$. Because $\alpha(B_i = r[A_i])$ there exists some pair $(a, b) \in \alpha(r) \cap \alpha(A_i) \times \alpha(q_j)$. Let $a \in p$ where $p \subseteq A_i$ is the cube containing $a$. Denote such cube $p_{ji}$ and repeat this process for all $1 \leq j \leq N$ and all $B_i$ where $q_j \subseteq B_i$ and let $C_{A0}$ be the resulting set of cubes $p_{ji}$. The set $C_{A0}$ has at most $NK$ elements, which is polynomially many.

In this process we have also identified a bipartite graph $E \subseteq C_{A0} \times C_B$

$$E = \{(p_{ji}, q_j) \mid 1 \leq j \leq N, \ 1 \leq i \leq K\}$$

*Observation about $E$*: If $(p, q) \in E$ and $p \subseteq A_i$, then $q \subseteq B_i$. *Proof:* Let $(p, q) \in E$ and $p \subseteq A_i$. By construction of $E$, for some witness elements $a \in \alpha(p)$, $b \in \alpha(q)$ we have $(a, b) \in \alpha(r)$. Because $\alpha(B_i = r[A_i])$, we have $b \in \alpha(B_i)$. Because $\alpha(q)$ and $\alpha(B_i)$ intersect, $q \subseteq B_i$, completing the proof of the observation.

We can now apply the sparse model construction of QFBAPA to the $F_A$ part to pick a sparse set of cubes $C_A \supseteq C_{A0}$. Treat again the values of integer variables in $F_A$ as constant, but then also in the resulting non-redundant integer cone generator replace the cardinalities of variables denoting sizes of each selected cube in $p \in C_{A0}$ by the constant $|\alpha(p)|$, thus removing these variables from the integer equation and removing the corresponding elements from the universe $\mathcal{U}_A$. Solve the remaining equations to obtain a sparse solution for the simplified $F_A$ formula, again using the results on sparse solutions of such Presburger arithmetic formulas [7,15]. We obtain a sparse solution that gives a polynomial number of non-empty cubes $C_{A1}$. We use the obtained values to define $\alpha_1(p)$ for $p \in C_{A1}$. We let $\alpha_1(p) = \alpha(p)$ for $p \in C_{A0}$. Let $C_A = C_{A0} \cup C_{A1}$. Define $\alpha_1(p) = \emptyset$ for $p \notin C_A$. This yields the sparse interpretation $\alpha_1$, where only cubes in $C_B \cup C_A$ are non-empty and where $\alpha_1(F_B \wedge F_A \wedge P)$ holds.

Finally, define define $\alpha_1(r)$ as a completed model $\alpha_1 = \bigcup \{p \times q \mid (p, q) \in E\}$ where $E$ is defined (by edges $(p_{ji}, q_j)$) above. We claim $\alpha_1(F_C)$. Indeed, consider a set $A_i$. Then $A_i$ is union of certain cubes from $C_{A0}$ and certain cubes from $C_{A1}$. Because $E$ has no outgoing edges for $C_{A1}$, we have $\alpha(r[\bigcup C_{A1}]) = \emptyset$. Therefore,

$$\alpha_1(r[A_i]) = \alpha_1(r[\cup\{p \mid p \in C_{A0}, p \subseteq A_i\}]) = \alpha_1(\cup\{q \mid \exists p. p \subseteq A_i \wedge (p, q) \in E\}$$

By the above *Observation about $E$*, we have that for each $q$ above (belonging to $E[\{p\}]$) the condition $q \subseteq B_i$ holds. Therefore $\alpha_1(r[A_i]) \subseteq \alpha(B_i)$. For the converse set inclusion, let $b \in \alpha_1(B_i)$ be arbitrary and let $q_j \in C_B$ be such that $b \in \alpha_1(q_j)$ and $q_j \subseteq B_i$. Note that $\alpha_1(p_{ji}) \neq \emptyset$, so there exists $a \in \alpha_1(p_{ji})$. Then $(a, b) \in \alpha_1(r)$. Because $p_{ji} \subseteq A_i$, we have $b \in \alpha_1(r[A_i])$. Thus, $\alpha(B_i) \subseteq \alpha_1(r[A_i])$

and the therefore $\alpha_1(r[A_i] = B_i)$. Because $i$ was arbitrary, $\alpha_1$ is a sparse model for the entire formula. ∎

**Theorem 6.** *The satisfiability for* QFBAPA-R2 *is NP complete.*

**Proof.** (Sketch) NP-hardness follows because QFBAPA-R2 subsumes propositional logic. To show NP membership, we use the sparse model property from the previous theorem: we non-deterministically guess a subset of non-empty sets $A_i$, then guess a polynomial subset $C_B$ of Venn regions over $B_i$, using the polynomial bounds from [15]. We then guess the subset $C_{A0}$ bounded by $K|C_B|$ and guess $C_{A1}$ conservatively bounded by the same bound as in [15]. Finally, we guess a graph $E$ whose number of edges is bounded by $|C_B|(|C_{A0}|+|C_{A1}|)$. Given such a guess, we can compute a formula that describes all Boolean Algebra expressions and all images of non-empty relations fragments under non-empty Venn regions, and thus describes the existence of a model for this guess of Venn regions and relation between them.

As in [15], the entire guessing process can be compiled into a polynomially large quantifier-free formula of Presburger arithmetic with conditional expressions. ∎

## 4.1 Extensions with Multiple Relations and Multiple Sorts

**NP extensions.** Consider any finite number of sorts $s_1, \ldots, s_n$ related by a strict total ordering, and any number of relations of sorts $s_i \times s_{i+1}$ for $0 \le i < n$. We can then repeat the construction above, starting with relations of sorts $s_{n-1} \times s_n$ and moving towards relations of sort $s_1 \times s_2$. For a fixed number of sorts, we obtain NP complexity. In fact, we can repeatedly apply the sparsity theorem in the case of multiple sorts and multiple relations forming a directed acyclic graph over the sorts. In that case, we start from the last sort in their topological ordering according to the direction of the relations.

**Limits of membership in NP.** Note that if we consider a chain of relations whose sorts form a cycle, through repeated composition we can simulate relations of sort $s \times s$. In this case the above NP construction fails. Moreover, the EXPTIME lower bound follows for such language from the lower bound on the complexity of the ALC Description Logic with general TBox inclusion axioms [1, Theorem 3.27], where we model $\wedge, \vee, \neg$ with $\cap, \cup, {\_}^c$, model $\exists R.A$ with $r[A]$, and model $\forall R.A$ with $r[A^c]^c$. To establish the correspondence of models of this extension and of the ALC formula, we interpret sets the same as the corresponding ALC concepts, and interpret the relation $r$ as the inverse of the corresponding role $R$.

## 5 Logic of Multiset Images of Functions

In this section we illustrate that some of the techniques of the previous section generalize from sets to *multisets*, which are unordered collections where elements

can repeat. Formally, a multiset $M$ is a function $M : E \rightarrow \mathbb{N}$ mapping the set of elements into the non-negative number of their occurrences. The first NP decision procedure for multisets with the cardinality operator was presented in [22]. In this section we extend the logic of multisets with cardinalities to also include a function image operator that maps a set into a multiset.

We define the function image of a set $A$ to be a multiset $f[A] : E \rightarrow \mathbb{N}$ such that $(f[A])(e) = |\{x.\ x \in A \land f(x) = e\}|$. Alternatively, let the disjoint union operator $\uplus$ be given by $(M_1 \uplus M_2)(e) = M_1(e) + M_2(e)$. (For example, $\{a, a, b\} \uplus \{a, b, c\} = \{a, a, a, b, b, c\}$.) Then define $f[\{e_1, \ldots, e_n\}] = \{f(e_1)\} \uplus \ldots \uplus \{f(e_n)\}$. It is easy to see that these two definitions are equivalent. Moreover, define the set of distinct elements occurring in a multiset by $\mathsf{set}(M) = \{x.\ M(x) > 0\}$. Then $\mathsf{set}(f[B])$ is the set corresponding to the standard notion of function image used in previous sections.

$$
\begin{aligned}
F &::= A \mid F \vee F \mid \neg F \\
A &::= B \subseteq B \mid M \subseteq M \mid T \leq T \mid K \text{ dvd } T \\
B &::= x \mid \emptyset \mid \mathcal{U} \mid B \cup B \mid B \cap B \mid B^c \mid \mathsf{set}(M) \\
M &::= m \mid \emptyset_M \mid M \cap M \mid M \cup M \mid M \uplus M \mid M \setminus M \mid M \setminus\!\!\setminus M \mid \mathsf{mset}(B) \mid f[B] \\
T &::= k \mid K \mid \mathsf{MAXC} \mid T_1 + T_2 \mid K \cdot T \mid |B| \mid |M| \\
K &::= \cdots \mid -2 \mid -1 \mid 0 \mid 1 \mid 2 \mid \cdots
\end{aligned}
$$

**Fig. 6.** MAPA-Fun logic of multisets, cardinality operator, and multiset images of sets

Figure 6 shows the logic that embeds the logic of multisets [21, Figure 1], [22], and extends it with the multiset image operator. The logic distinguishes the sorts of sets and multisets and defines set operators on both sets and multisets. Note, however, that the logic includes the embedding function $\mathsf{mset}(B)$ to view a set as a multiset, and the abstraction function $\mathsf{set}(M)$ to extract the set of distinct elements that occur in the multiset. Unlike the previous section, we do not have disjointness of domains and ranges of functions, and, in terms of expressive power, we effectively treat sets as a special case of multisets.

Given a formula $F$ in the language described in Figure 6, a decision procedure for $F$ works as follows:

1. Apply the algorithm in Figure 7 to translate $F$ into an equisatisfiable multiset formula $F'$ in the syntax given in Figure 1 in [21]. In this step we eliminate function symbols in a way similar to that described in Section 3. The new formula $F'$ has size singly exponential in the size of $F$;
2. invoke on the formula $F'$ the decision procedure described in [22]. The decision procedure runs in NP time.

The entire procedure runs in NEXPTIME. The lower bound proof from Section 3.2 applies in this case as well, so we conclude that our logic is NEXPTIME-complete.

The correctness of the reduction is stated in the following theorem.

14

**INPUT:**     formula in the syntax of Figure 6
**OUTPUT:** multiset formula in the syntax of Figure 1 in [21]

1. For each set variable $S$ introduce a conjunct $\forall e.\ S(e) = 0 \vee S(e) = 1$
2. Flatten expressions containing the operator set:
   $$C[\ldots \mathsf{set}(M)\ldots] \rightsquigarrow (B_F = \mathsf{set}(M) \wedge C[\ldots B_F \ldots])$$
   where the occurrence of $\mathsf{set}(M)$ is not already in a top-level conjunct of the form $B = \mathsf{set}(M)$ for some set variable $B$ and $B_F$ is a fresh unused set variable
3. Let $S$ be the set of variables occurring in the formula
   Define the set $S_N = \{s_1, \ldots, s_Q\}$ of Venn regions over elements of $S$
4. Rewrite each set expression as a disjoint union of the appropriate Venn regions from $S_N$
5. **Eliminate function symbols:**
   $$C[\ldots f[s_{i_1} \cup \ldots \cup s_{i_k}]\ldots] \rightsquigarrow C[\ldots (M_{i_1} \uplus \ldots \uplus M_{i_k})\ldots]$$
   where each $M_{i_j}$ is a fresh multiset variable denotes $f[s_{i_j}]$
6. Add the conjuncts which states a necessary condition for $M_{i_j} = f[s_{i_j}]$
   $$F \quad \rightsquigarrow \quad F \wedge \bigwedge_{i=1}^{Q} |s_i| = |M_i|$$

**Fig. 7.** Algorithm for reducing a MAPA-Fun formula to a MAPA formula

**Theorem 7.** *Given a formula $F$ as an input to the algorithm described in Figure 7, let the formula $F'$ be its output. Then formulas $F$ and $F'$ are equisatisfiable and their satisfying assignments have the same projections on the set and multiset variables occurring in $F$.*

**Proof.** Given a model for $F$, we construct a model for $F'$ by interpreting $M_i$ as $f[s_i]$. Conversely, let $\alpha$ be a model for $F'$. We can define $f$ on each disjoint set $s_i$ independently. Because $|s_i| = |M_i|$ holds in the model, we can enumerate both $s_i$ and $M_i$ into sequences $a_1, \ldots, a_K$ and $b_1, \ldots, b_K$ of same length. This enumeration defines a function assigning $a_j$ to $b_j$ for $1 \leq j \leq K$ such that $f[s_i] = M_i$. ∎
