FUNDAMENTAL GROUPS OF SYMMETRIC SEXTICS. II

ALEX DEGTYAREV

Abstract. We study the moduli spaces and compute the fundamental groups of plane sextics of torus type with the set of inner singularities $2A_8$ or $A_{17}$. We also compute the fundamental groups of a number of other sextics, both of and not of torus type. The groups found are simplest possible, i.e., $Z_2 \ast Z_3$ and $Z_6$, respectively.

1. Introduction

1.1. Principal results. This work concludes the series of papers [8], [9], [10], where we attempt to classify and to compute the fundamental groups of irreducible plane sextics of torus type. Recall that a sextic $B$ is said to be of torus type if its equation can be represented in the form $p^3 + q^2 = 0$, where $p$ and $q$ are certain homogeneous polynomials of degree 2 and 3, respectively. Alternatively, $B \subset \mathbb{P}^2$ is of torus type if and only if it is the ramification locus of a projection to $\mathbb{P}^2$ of a cubic surface in $\mathbb{P}^3$. A representation of the equation in the form $p^3 + q^2 = 0$ (up to the obvious equivalence) is called a torus structure of $B$. A singular point $P$ of $B$ is called inner (outer) with respect to a torus structure $(p, q)$ if $P$ does (respectively, does not) belong to the intersection of the conic $\{p = 0\}$ and the cubic $\{q = 0\}$. Each sextic $B$ considered in this paper has a unique torus structure, see [5]; hence, we can speak about inner and outer singular points of $B$. To indicate the difference, we will use the notation $(\Sigma_{\text{inner}}) \oplus \Sigma_{\text{outer}}$ in the listings. (Note that simple singular points of a sextic are conveniently identified with their resolution lattices in the homology of the covering $K3$-surface; for this reason, we use the direct summation symbol $\oplus$ in the notation.)

Another special class is formed by the so called $D_{2n}$-sextics, i.e., irreducible plane sextics whose fundamental group factors to the dihedral group $D_{2n}$. Due to [5], the $D_{2n}$-sextics are precisely those of torus type (see also [24]), and the other possible values are $n = 5$ or 7. All $D_{20}$- and $D_{14}$-sextics are classified and most fundamental groups are computed in [7] (see also [14]) and [11].

First, sextics of torus type appeared in O. Zariski [25]. For the modern state of the subject and further references, see M. Oka, D. T. Pho [20], [21], H. Tokunaga [23], and A. Degtyarev [5]. According to [25], the fundamental group $\pi_1(\mathbb{P}^2 \setminus B)$ of any sextic of torus type factors to the reduced braid group $\mathbb{B}_3 := \mathbb{B}_3/(\sigma_1\sigma_2)^3 \cong \text{PSL}(2, \mathbb{Z}) \cong \mathbb{Z}_2 \ast \mathbb{Z}_3$ (which is the group of the ‘simplest’ curve, the six cuspidal sextic, constructed in [25]). We show that, in fact, for most irreducible sextics of torus type, the group equals $\mathbb{B}_3$. (A summary of known cases is found in Section 7.1. At present, there are 15 sets of singularities for which the group is still unknown.)
Our principal results in this paper are Theorems 1.1.1 and 1.1.3 below, classifying and computing the fundamental group of sextics with the set of singularities \((2A_8)\) and their degenerations.

1.1.1. Theorem. An irreducible plane sextic of torus type with inner singular points \(2A_8\) or \(A_{17}\) has one of the following eight sets of singularities:

\[
\begin{align*}
(A_{17}) &\oplus A_2, & (A_{17}) &\oplus A_1, & (A_{17}), \\
(2A_8) &\oplus A_3, & (2A_8) &\oplus A_2, & (2A_8) &\oplus 2A_1, & (2A_8) &\oplus A_1, & (2A_8).
\end{align*}
\]

The moduli space of irreducible sextics of torus type realizing each of the sets of singularities above is unirational; in particular, it is connected.

To complete Theorem 1.1.1, we also consider reducible sextics of torus type with a type \(A_{17}\) singular point; they split into two cubics.

1.1.2. Theorem. A reducible plane sextic of torus type with a type \(A_{17}\) singular point has one of the following four sets of singularities:

\[
\begin{align*}
(A_{17}) &\oplus A_2, & (A_{17}) &\oplus 2A_1, & (A_{17}) &\oplus A_1, & (A_{17}).
\end{align*}
\]

Each of these sets of singularities is realized by a single connected deformation family of reducible plane sextics of torus type.

Theorems 1.1.1 and 1.1.2 are proved in Sections 2.4 and 5.3, respectively. Another family of reducible sextics of torus type, those splitting into a quartic and a conic, is considered in §5, see Theorems 5.1.1 and 5.2.1.

1.1.3. Theorem. The fundamental group \(\pi_1(\mathbb{P}^2 \setminus B)\) of each plane sextic \(B\) as in Theorem 1.1.1 equals \(\mathbb{B}_3\).

This theorem is proved in Section 3.6.

1.2. Other results. In the proof of Theorems 1.1.1 and 1.1.3, we use the approach of [7], [8], [10] (see also Oka [18]), representing the sextics in question as double coverings of a certain rigid (maximal in the sense of [4]) trigonal curve \(\tilde{B}\) in the Hirzebruch surface \(\Sigma_2\) (see Section 2.1). According to [9], there are four maximal trigonal curves admitting a torus structure. Two of them are studied in [8] and [10], one is considered here (see \(\tilde{B}_1\) in Section 2.2), and the fourth one is reducible (see \(\tilde{B}_2\) in Section 2.5). We extend to the remaining reducible curve \(\tilde{B}_2\) the results of [9] and show that it corresponds to sextics of torus type splitting into a quartic and a conic, see Theorem 5.1.1 for the precise statement. As a consequence, we obtain a deformation classification of such reducible sextics, see Theorem 5.2.1, and compute their fundamental groups, see §4. However, we do not make any attempt to simplify the presentations obtained; we merely summarize the results in Theorem 5.2.3 and Remark 5.2.4.

The double covering construction involving the reducible curve \(\tilde{B}_2\) makes use of two sections: the linear component of \(\tilde{B}_2\) and the ramification locus. Interchanging the sections, we obtain another family of reducible sextics whose groups are found with almost no extra work, see §6. The geometry of these curves is briefly discussed in Section 6.6; it involves yet another pair of reducible maximal trigonal curves found in [9].
Instead of simplifying the groups of reducible sextics, we perturb the curves and obtain the groups of irreducible ones. The perturbations are constructed using Proposition 5.1.1 in [8], stating that any induced subgraph of the combined Dynkin graph of a sextic $B$ can be realized by a perturbation of $B$. This procedure gives rise to a few new sextics of torus type (the items marked as ‘see 4.7’ in Table 1 in §7) and a number of sextics not of torus type (Table 3 in §7). Incorporating the results of [8] and [10], we obtain the fundamental groups of all but 15 irreducible sextics of torus type (most of the groups are $\mathbb{B}_3$, see Section 7.1 for details) and 768 other sextics not covered by M. V. Nori’s theorem [17] (all groups are abelian). Extremal (in the sense of this paper, i.e., not degenerating to a larger set of singularities with known fundamental group) sets of singularities with known groups are listed in §7.

Strictly speaking, for most configurations of singularities, the connectedness of the equisingular moduli space is still unknown. For this reason, we state most results in the form of existence only. However, there is a strong arithmetical evidence for the following conjecture, which would imply the connectedness.

1.2.1. Conjecture. The equisingular moduli space of irreducible plane sextics with any non-maximal configuration of simple singularities is connected.

Here, the configuration of singularities is the set of singularities enriched with certain information on the mutual position of the singular points, see [3] for the precise definition. According to [5], in the case of irreducible sextics, all extra information needed is whether the curve is or is not a $\mathbb{D}_n$-sextic for some $n$. A configuration of singularities is non-maximal if it extends to a larger configuration of singularities still realized by plane sextics.

1.3. Contents of the paper. In §2, we explain the double covering construction used in the proofs, introduce the maximal trigonal curves $B_1$ and $B_2$, and study the sections of $\Sigma_2$ that are in a special position with respect to one of these curves. Theorem 1.1.1 is proved here.

§3 deals with the proof of Theorem 1.1.3. We sketch out Zariski-van Kampen’s method [15] in the special case of the ruling of $\Sigma_2$ (section 3.1), explain how the braid monodromy is computed (Section 3.2), and compute the groups of the two maximal sextics (Sections 3.3 and 3.4). Then, we study the local perturbations of a few simple singularities (Section 3.5) and global perturbations of sextics of torus type (Section 3.6), computing the groups of the other sextics listed in Theorem 1.1.3.

In §4, we compute the groups of sextics of torus type splitting into a quartic and a conic (using the same approach as in §3). In §6, the representations obtained are modified to produce the groups of a few other reducible sextics. In all cases, we are only interested in the curves whose perturbations contain new irreducible sextics.

§5 is a digression: we establish a geometric correspondence between the curve $B_2$ and sextics of torus type splitting into a quartic and a conic (Theorem 5.1.1). As a consequence, we give a complete classification of such sextics, see Theorem 5.2.1. Theorem 1.1.2 is also proved here.

In §7, we give a brief summary of the results of [8], [10], and this paper. In particular, we give a list of the 15 sets of singularities of sextics of torus type, for which the fundamental group is still unknown, and discuss the so-called classical Zariski pairs (Section 7.3).

1.4. Acknowledgements. An essential part of this work was completed during my participation in the special semester on Real and Tropical Algebraic Geometry
2. The trigonal models

In Section 2.1, we explain the double covering construction used to produce symmetric plane sextics from trigonal curves in the Hirzebruch surface $\Sigma_2$. Then, we study two particular rigid trigonal curves $\bar{B}_1$ and $\bar{B}_2$, with the sets of singularities $A_5$ and $A_3 \oplus A_3 \oplus A_1$, respectively. Most calculations below are straightforward; they were done using Maple.

Note that, according to [9], there are four maximal trigonal curves in $\Sigma_2$ that admit a torus structure. Two of them are considered in [8] and [10]; the curves $\bar{B}_1$ and $\bar{B}_2$ studied here are the remaining two.

2.1. The double covering construction. Denote by $\Sigma_2 \to \mathbb{P}^1$ the Hirzebruch surface (i.e., geometrically ruled rational surface) with an exceptional section $E$ of self-intersection $(-2)$. (One can think of $\Sigma_2$ as the minimal resolution of singularities of the quadratic cone in $\mathbb{P}^3$.) When speaking about affine coordinates $(x, y)$ in $\Sigma_2$, we always assume that $E$ is given by $y = \infty$.

Any section of $\Sigma_2$ disjoint from $E$ has the form

$$(2.1.1) \quad y = s(x) := ax^2 + bx + c, \quad a, b, c \in \mathbb{C}.$$ 

Given such a section $L$, the double covering of the cone $\Sigma_2/E$ ramified at $E/E$ and $L$ is the projective plane $\mathbb{P}^2$, and the deck translation of the covering is an involutive automorphism $c: \mathbb{P}^2 \to \mathbb{P}^2$. Conversely, any involution $c: \mathbb{P}^2 \to \mathbb{P}^2$ has a fixed line $L_c$ and an isolated fixed point $O_c$, and the quotient $\mathbb{P}^2(O_c)/c$ is the Hirzebruch surface $\Sigma_2$. (Here, $\mathbb{P}^2(O_c)$ stands for the plane $\mathbb{P}^2$ blown up at $O_c$.)

For the purpose of this paper, a trigonal curve is a curve $\bar{B} \subset \Sigma_2$ disjoint from $E$ and intersecting each fiber at three points. (Alternatively, $\bar{B}$ is a curve in $\mathbb{P}^3$ not containing $E$, where $F$ is a fiber.) Any trigonal curve is given by a polynomial of the form

$$(2.1.2) \quad f(x, y) := y^3 + r_2(x)y^2 + r_4(x)y + r_6(x), \quad \deg r_i = i.$$ 

A torus structure on the trigonal curve given by (2.1.2) is a decomposition of the form

$$(2.1.3) \quad f(x, y) = (y + q_2(x))^3 + (q_4(x)y + q_6(x))^2, \quad \deg q_i = i.$$ 

A trigonal curve admitting a torus structure is said to be of torus type.

Given a trigonal curve $\bar{B}$ and a section $L$ not contained in $\bar{B}$, the pull-back of $B$ under the double covering $\mathbb{P}^2 \to \Sigma_2/E$ ramified at $E/E$ and $L$, see above, is a plane sextic $\bar{C} \subset \mathbb{P}^2$; we denote it by $\text{Db}(\bar{B})$ and call it the double of $\bar{B}$ ramified at $L$.

In appropriate affine coordinates $(x, y)$ in $\mathbb{P}^2$, the double is given by the equation

$$(2.1.4) \quad f(x, y^2 + s(x)) = 0,$$

where $f$ and $s$ are as in (2.1.2) and (2.1.1), respectively. If $\bar{B}$ is of torus type, so is $\text{Db}(\bar{B})$ for any section $L$. The relation between the singularities of $\bar{B} + L$ and those of $\text{Db}(\bar{B})$ is studied in [7].

The sextic $\bar{B} = \text{Db}(\bar{B})$ has an involutive symmetry, i.e., an automorphism $c: \mathbb{P}^2 \to \mathbb{P}^2$ preserving $\bar{B}$. Conversely, any sextic $\bar{B}$ with an involutive symmetry $c$ such that $O_c \notin \bar{B}$ is the double of a trigonal curve.
2.2. The curve $\bar{B}_1$ (the set of singularities $A_8$). The trigonal curve $\bar{B}_1 \subset \Sigma_2$ with the set of singularities $A_8$ is a maximal trigonal curve in the sense of [4]; its skeleton is shown in Figure 1, left. Alternatively, $\bar{B}_1$ can be obtained by a birational transformation from a plane quartic with a type $A_8$ singular point. The curve is plotted (in black) in Figures 3 and 4 below.

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{figure1}
\caption{The skeletons of $\bar{B}_1$ and $\bar{B}_2$.}
\end{figure}

In appropriate affine coordinates $(x, y)$ in $\Sigma_2$, the curve is given by the polynomial

\[(2.2.1) \quad f_1(x, y) := -y^3 + y^2 - x^3(2y - x^3).\]

It has a unique torus structure, given by

\[f_1(x, y) = (-y)^3 + (y - x^3)^2,\]

and a parametrization

\[x = x_t := \frac{t}{t^3 + 1}, \quad y = y_t := \frac{1}{(t^3 + 1)^2}.\]

The discriminant of $f_1$ with respect to $y$ is $-x^9(27x^3 - 4)$. Thus, $\bar{B}_1$ has a type $A_8$ singular point $P_0 = (0, 0)$ (corresponding to $t = \infty$) and three vertical tangency points

\[P_1 = \left(\frac{\sqrt[3]{4}}{3}, -\frac{4}{9}\right), \quad P_{\pm} = \left(\epsilon_{\pm}, \frac{\sqrt[3]{4}}{3}, -\frac{4}{9}\right)\]

(corresponding to the roots of the equation $2t^3 = 1$), where $\epsilon_{\pm} = (-1 \pm i\sqrt{3})/2$ are the primitive cubic roots of unity.

The surface $\Sigma_2$ has three automorphisms $(x, y) \mapsto (\epsilon x, y), \epsilon^3 = 1$, preserving $\bar{B}_1$ (the symmetries of $\bar{B}_1$) and three real structures $\text{conj}_i : (x, y) \mapsto (\epsilon^2 x, y), \epsilon^3 = 1$, with respect to which $\bar{B}_1$ is real. The real part (i.e., the fixed point set) of $\text{conj}_i$ is $(:e_0, R, R)$. In the sequel, we use the abbreviation $\text{conj} := \text{conj}_1$ and $\text{conj}_{\pm} := \text{conj}_{\pm}$. It is easy to see that a conj-real section (2.1.1), $a, b, c \in \mathbb{R}, a \neq 0$, intersects the real part ($e_0, R, R$) of $\text{conj}_{\pm}$ at two points: $(0, c)$ and $\left(\epsilon_{\pm}, -\frac{b}{a}, -\frac{c}{a}\right)$. (If $a = 0$ and $b \neq 0$, the only intersection point is $(0, c)$. If $a = b = 0$, the section is real with respect to all three real structures.)

2.3. Special sections. Pick a section $\tilde{L}$ and consider the double $B = \text{Dbl}_L \bar{B}_1$. It is a sextic of torus type, see 2.1. If $\tilde{L}$ is generic, the set of singularities of $B$ is $(2A_8)$; otherwise, the singularities of $B$ are recovered from those of $\bar{B}_1 + \tilde{L}$ using the results of [7]. Below, for each configuration of $\bar{B}_1 + \tilde{L}$, we parametrize the space
of sections $\tilde{\mathcal{L}}$ that are in the desired position with respect to $\tilde{B}_1$: for the reader’s convenience, we also indicate the corresponding set of singularities of $B$.

A section (2.1.1) passes through the cusp $P_0$ of $\tilde{B}_1$ (the set of singularities $(\mathbb{A}_{17})$) if and only if $c = 0$.

A section (2.1.1) is tangent to $\tilde{B}_1$ at a point $(x(t), y(t))$, $2t^3 \neq 1$, (the set of singularities $(2\mathbb{A}_8) \oplus \mathbb{A}_1$) if and only if $t^3 \neq -1$ and

$$b = -\frac{2t(2t^3 - 1)a - 6t^2}{(2t^3 - 1)(t^3 + 1)}, \quad c = \frac{t^2(2t^3 - 1)a - (4t^3 + 1)}{(2t^3 - 1)(t^3 + 1)^2}$$

or $t^3 = -1$ and $a = -t$, $b = -2t^2/3$. Such a section passes through the cusp $P_0$ (the set of singularities $(\mathbb{A}_{17}) \oplus \mathbb{A}_1$) if and only if

$$a = \frac{4t^3 + 1}{t^2(2t^3 - 1)}, \quad b = -\frac{2}{t^2(2t^3 - 1)}, \quad c = 0.$$

A section (2.1.1) is inflection tangent to $\tilde{B}_1$ at a point $(x(t), y(t))$, $2t^3 \neq 1$, (the set of singularities $(2\mathbb{A}_8) \oplus \mathbb{A}_2$) if and only if

$$a = \frac{3t(8t^6 + t^3 + 2)}{(2t^3 - 1)^3}, \quad b = -\frac{6t^2(4t^3 + 1)}{(2t^3 - 1)^3}, \quad c = \frac{8t^3 - 1}{(2t^3 - 1)^3}.$$

There are three inflection tangents passing through the cusp $P_0$ of $\tilde{B}_1$ (the set of singularities $(\mathbb{A}_{17}) \oplus \mathbb{A}_2$):

$$(2.3.2) \quad t = \frac{\epsilon}{2}, \quad (a, b, c) = \left(-8\epsilon, \frac{16\epsilon^2}{3}, 0\right), \quad \epsilon^3 = 1.$$

Clearly, the three tangents (2.3.2) are interchanged by the symmetries of $B_1$. The tangent $\tilde{L}$ corresponding to the real value $\epsilon = 1$ is conj-real; it is shown in grey in Figure 3 below. The tangent intersects $\tilde{B}_1$ at $P_0$ and the following two points:

- inflection tangency at $t = \frac{1}{2}$, $(x, y) = \left(\frac{4}{9}, \frac{64}{81}\right) \approx (0.44, 0.79)$;
- transversal intersection at $t = \frac{3}{2}$, $(x, y) = \left(\frac{12}{19}, \frac{64}{361}\right) \approx (0.63, 0.78)$.

The intersection of $\tilde{L}$ with the real part $\text{Fix}_{\text{conj}_+}$ is at $(x, y) = \left(-\frac{2\epsilon}{3}, \frac{32}{9}\right)$.

Next lemma deals with the case when a section $\tilde{L}$ as in (2.1.1) is double tangent to $B_1$ (the set of singularities $(2\mathbb{A}_8) \oplus 2\mathbb{A}_1$).

**2.3.3. Lemma.** There exists a section $\tilde{L}$ of $\Sigma_3$ tangent to $B_1$ at two distinct points $(x_i(t_i), y_i(t_i)), i = 1, 2, t_1 \neq t_2, 2t_i^3 \neq 1$, if and only if $2(t_1 + t_2)^3 = -1$. A pair $t_1, t_2$ above determines the double tangent $\tilde{L}$ uniquely.

**Proof.** It suffices to substitute $t = t_1$ and $t = t_2$ to (2.3.1), equate the resulting expressions for $b$ and $c$, and solve for $a$ the linear system obtained. The relation $2(t_1 + t_2)^3 = -1$ is the condition for the compatibility of the two equations.

Letting $t_1 = t_2$ in Lemma 2.3.3, we obtain three sections having a point of quadruple intersection with $\tilde{B}_1$ (the set of singularities $(2\mathbb{A}_8) \oplus \mathbb{A}_3$):

$$(2.3.4) \quad t = \frac{\delta}{2}, \quad (a, b, c) = \left(-\frac{56\delta}{27}, \frac{64\delta^2}{81}, \frac{256}{243}\right), \quad \delta^3 = -\frac{1}{2}.$$
The three sections (2.3.4) are interchanged by the symmetries of $\hat{B}_1$. The section $\hat{L}$ corresponding to the real value $\delta = -\sqrt{3}/2$ is conj-real; it is shown in grey in Figure 4 below. This section intersects $\hat{B}_3$ at the following points:

- quadruple intersection at $t = -\sqrt{4}$ over $x = -\frac{4\sqrt{4}}{15} \approx -0.42$;
- transversal intersection at $t = \left(\frac{1}{2} \pm \frac{3}{4}i\right) \sqrt{4}$ over $x = -\left(\frac{44}{327} \pm \frac{48}{109}i\right) \sqrt{4}$.

The intersection of $\hat{L}$ with Fix conj is at $(x, y) = \left(\frac{4\sqrt{4}e_+}{21}, \frac{512}{567}\right) \approx (0.30e_+, 0.90)$. Note that the three points of $\hat{B}_1$ in the fiber over $x = 4\sqrt{4}e_/21$ are $y \approx 0.024$, 0.034, and 0.94.

2.4. Proof of Theorem 1.1.1. Let $\Sigma$ be a set of singularities as in Theorem 1.1.1, and let $\mathcal{M}(\Sigma)$ be the moduli space of irreducible sextics of torus type realizing $\Sigma$. Due to [9], each sextic $\hat{B}$ in question has a unique involutive stable symmetry $c$, and the quotient $B/c$ is a trigonal curve $B \subset \Sigma_2$ with a single singular point of type $A_6$. Conversely, one has $B = \text{Db}_{\Sigma} \hat{B}$ for an appropriate section $L$ (the image of $L_c$). Hence, $\mathcal{M}(\Sigma)$ can be identified with the moduli space of pairs $(B, L)$, where $B \subset \Sigma_2$ is a trigonal curve with the set of singularities $A_6$ and $L$ is a section of $\Sigma_2$ in a certain prescribed position with respect to $B$. Furthermore, since any curve $\hat{B}$ as above is isomorphic to the curve $\hat{B}_1$ considered in Section 2.2 (see [9]) and the group of symmetries of $\hat{B}_1$ is $Z_3$, there is a cyclic triple ramified covering $\mathcal{M}(\Sigma) \rightarrow \mathcal{M}(\Sigma)$, where $\mathcal{M}(\Sigma)$ is the space of sections $L$ forming a prescribed configuration with $\hat{B}_1$.

The spaces $\mathcal{M}(\Sigma)$ are described in Section 2.3. In each case, $\mathcal{M}(\Sigma)$ either is rational or consists of three rational components (for $\Sigma = (A_5 \oplus A_2), (2A_3) \oplus A_3$, or $(2A_5) \oplus 2A_1$). In the former case, $\mathcal{M}(\Sigma)$ is unirational; in the latter case, the three components are interchanged by the symmetries of $\hat{B}_1$ (the deck translation of the covering) and hence $\mathcal{M}(\Sigma)$ is rational. □

2.5. The curve $B_2$ (the set of singularities $(A_5 \oplus A_2) \oplus A_1$). The trigonal curve $B_2 \subset \Sigma_2$ with the set of singularities $(A_5 \oplus A_2) \oplus A_1$ is a maximal trigonal curve; its skeleton is shown in Figure 1, right, and the curve is plotted (in black) in Figures 8–11 below. Alternatively, the curve $B_2$ can be obtained by a birational transformation from a pair of conics inflection tangent to each other or from a plane quartic splitting into a cuspidal cubic and a tangent to it. In inappropriate affine coordinates $(x, y)$ in $\Sigma_2$, the curve is given by the polynomial

$$f_2(x, y) = (y^2 - x)(y - l(x)), \quad \text{where} \quad l(x) = -x^2 + \frac{3}{2}x + \frac{3}{16}.$$  

It splits into a hyperelliptic curve $B'_2 = \{x = y^2\}$ with a cusp $R_\infty$ over $x = \infty$ and a section $L' = \{y = l(x)\}$. The two components have a point of inflection tangency at $R_5 = (1/4, 1/2)$ and a point of transversal intersection at $R_1 = (9/4, -3/2)$, forming the singular points of $B_2$ of types $A_5$ and $A_1$, respectively. The only torus structure of $B_2$ is given by

$$64f_2(x, y) = (4y - 4x - 1)^3 + (8xy + 6y - 12x - 1)^2.$$  

Pick a section $\hat{L}$ as in (2.1.1) and consider the sextic $B = \text{Db}_{\Sigma} \hat{B}_2$. It is of torus type, see 2.1. Furthermore, $B$ splits into a quartic $B_4$ and conic $\hat{B}_2$ (the pull-backs
of $\bar{B}_2'$ and $\bar{L}'$, respectively), which may further be reducible. If $\bar{L}$ is generic, $B_4$ has two cusps and two points of inflection tangency with $B_2$.

A section $\bar{L}$ as in (2.1.1) is inflection tangent to $\bar{B}_2'$ at a point $(t^2, t)$, $t \neq 0$ (the quartic $B_4$ has three cusps) if and only if

$$ (a, b, c) = \left( -\frac{1}{8t^3}, \frac{3}{4t}, \frac{3t}{8} \right). $$

Such a section passes through $R_5$ if and only if

$$ (a, b, c) = \left( 27, -\frac{9}{2}, -\frac{1}{16} \right). $$

(2.5.1)

It is shown in grey in Figure 8 below (where $R_1$ is missing). The section is inflection tangent to $\bar{B}_2'$ at $Q_5 = (1/36, -1/6)$ and intersects $\bar{L}'$ at $Q_1 = (-1/28, 13/98)$. The double $B$ has the set of singularities $(A_{11} \oplus 2A_2) \oplus A_2 \oplus 2A_1$; it splits into a three cuspidal quartic and a conic.

Making $\bar{L}'$ and $\bar{L}$ trade roles, i.e., considering the sextic given by

$$ ((y^2 + l(x))^2 - x)(y^2 + l(x) - s(x)) = 0, $$

(2.5.2)

we obtain a curve $B = Dbl_{\bar{L}}(\bar{B}_2' + \bar{L})$ with the set of singularities $(2A_5 \oplus 2A_2) \oplus D_4$, also splitting into a three cuspidal quartic and a conic. (Note that $B$ is still of torus type, as the trigonal curve $\bar{B}_2' + \bar{L}$ is isomorphic to $\bar{B}_2$ via $(x, y) \rightarrow (9x, -3y)$.)

A section $\bar{L}$ passes through $R_5$ and is tangent to $\bar{B}_2'$ at $R_1$ if and only if

$$ (a, b, c) = \left( 1, -\frac{11}{6}, \frac{15}{16} \right). $$

(2.5.3)

It is shown in grey in Figure 9 below. (There is an extra point $Q_1 = (25/4, 5/2)$ of transversal intersection of $\bar{L}$ and the upper branch of $\bar{B}_2'$; it is missing in the figure.) The double $B$ has the set of singularities $(A_{11} \oplus 2A_2) \oplus D_4$; it splits into a quartic with the set of singularities $2A_2 \oplus A_1$ and a conic.

The section $\bar{L}$ passing through $R_5$ and tangent to $\bar{B}_2'$ at $R_\infty$ is given by

$$ y = 1/2, $$

(2.5.4)

see the solid grey line in Figure 10. The section intersects $\bar{L}'$ transversally at a point $Q_1 = (5/4, 1/2)$. The double $B$ has the set of singularities $(E_6 \oplus A_{11}) \oplus 2A_1$; it splits into a quartic with a type $E_6$ singular point and a conic.

The section $\bar{L}$ passing through $R_1$ and tangent to $B$ at $R_\infty$ is given by

$$ y = -3/2, $$

(2.5.5)

see the dotted grey line in Figure 10. The section intersects $\bar{L}'$ transversally at a point $Q_1 = (-3/4, -3/2)$. The double $B$ has the set of singularities $(E_6 \oplus 2A_5) \oplus A_3$; it splits into a quartic with a type $E_6$ singular point and a conic.

A section $\bar{L}$ passes through $R_\infty$ and is tangent to $\bar{B}_2'$ at $R_1$ if and only if

$$ (a, b, c) = \left( 0, -\frac{1}{3}, \frac{3}{4} \right). $$

(2.5.6)
see the solid grey line in Figure 11. The section intersects \( \tilde{L}' \) transversally at the point \( Q_1 = (-5/12, -11/18) \). The double \( B \) has the set of singularities \((3A_5) \oplus D_4\), splitting into three conics inflection tangent to each other and having a common point.

A section \( \tilde{L} \) passes through \( P_1, P_3, \) and \( R_{\infty} \) if and only if
\[
(a, b, c) = \left(0, -1, \frac{3}{4}\right),
\]
see the dotted grey line in Figure 11. The double \( B \) has the set of singularities \((A_{11} \oplus A_5) \oplus A_3\); it splits into a quartic with a type \( A_5 \) singular point and a conic.

### 2.6. Other degenerations

Here, we consider other possible degeneration of a section \( \tilde{L} \) with respect to \( \tilde{B}_2 \), each time showing that the space of sections admits a rational parametrization. We omit obviously linear conditions, like passing through one or several of the points \( R_1, R_5, R_{\infty} \).

As above, we fix the notation \( B = \text{Dbl}_\beta \tilde{B}_2 \) and the splitting \( B = B_4 + B_2 \) into the pull-backs of \( B_2' \) and \( \tilde{L}' \), respectively.

A section \( \tilde{L} \) is tangent to \( B_2' \) at a point \((t^2, t), \ t \neq 0\). (the quartic \( B_4 \) has an extra node) if and only if
\[
b = -\frac{4at^3 - 1}{2t}, \quad c = at^4 + \frac{1}{2}t.
\]
Such a section passes through \( R_5, R_1, \) or \( R_{\infty} \) if and only if, respectively,
\[
a = -\frac{2}{t(2t + 1)^2}, \quad a = -\frac{2}{t(2t - 3)^2}, \quad \text{or} \quad a = 0.
\]
(The corresponding degenerations of \( B \) are, respectively, the confluence of two points of inflexion tangency of \( B_4 \) and \( B_2 \) into a single point of 6-fold intersection, the confluence of two points of transversal intersection of \( B_4 \) and \( B_2 \) into a single tacnode \( A_3 \), and the confluence of two cusps of \( B_4 \) into a single type \( A_5 \) singular point.) The section \( \tilde{L} \) cannot pass through two of the points \( R_5, R_1, R_{\infty} \) unless one of them is the tangency point.

A section \( \tilde{L} \) is tangent to the \( \tilde{L}' \) component of \( \tilde{B}_2 \) (the conic \( B_2 \) splits into two lines) if and only if \(-16ac + 3a + 4b^2 - 12b - 16c + 12 = 0\). (Clearly, this equation defines a rational subvariety in the space of triples \((a, b, c)\).) Such a section cannot pass through \( R_5 \) or \( R_1 \) (unless it is the tangency point); it passes through \( R_{\infty} \) if and only if \( a = 0 \) and \( 4c = b^2 - 3b + 3 \).

A section tangent to \( B_2' \) at \((t^2, t) \) is also tangent to \( \tilde{L}' \) if and only if
\[
a = -\frac{1}{t^2(2t + 3)}, \quad b = \frac{3(2t + 1)}{2t(2t + 3)}, \quad c = \frac{3t}{2(2t + 3)}.
\]
When \( t \to \infty \), it tends to the section \( y = 3/4 \) tangent to \( B_2' \) at \( R_{\infty} \) and tangent to \( \tilde{L}' \) (the set of singularities \((E_6 \oplus 2A_5) \oplus 3A_1\)).

### 3. Proof of Theorem 1.1.3

In the rest of the paper, we compute the fundamental groups \( \pi_1(\mathbb{P}^2 \setminus B) \) of various sextics \( B \) of the form Dbl\( \beta \tilde{B} \), see 2.1. We start with \( B = \tilde{B}_1 \), see 2.2.

Sections 3.1 and 3.2 contain an outline of the approach used to compute the groups. In 3.3 and 3.4, we study the two maximal doubles of \( \tilde{B}_1 \). In 3.5, we discuss the perturbations of a few simple singular points. These results are applied in 3.6 to prove Theorem 1.1.3.
3.1. Preliminaries. Let $\hat{B} = \hat{B}_1 \subset \Sigma_2$ be the trigonal curve as in 2.2, and let $\hat{L}$ be a section of $\Sigma_2$. We start with the group $\pi_1 := \pi_1(\Sigma_2 \setminus (\hat{B}_1 \cup \hat{L} \cup E))$ and compute it, applying the classical Zariski–van Kampen method [15] to the ruling of $\Sigma_2$ (the pencil $\{x = \text{const}\}$ in the notation of §2).

Pick and fix a real section $S = \{y = \text{const} \gg 0\}$ of $\Sigma_2$ and a real nonsingular fiber $F = \{x = \tau\}$, where $\tau > 0$ is sufficiently small. Let $P = F \cap S$, and pick a basis $\alpha, \beta, \gamma, \delta$ for the group $\pi_F := \pi_1(F \setminus (\hat{B}_1 \cup \hat{L} \cup E), P)$ as shown in black in Figure 2, left. (In all cases considered below, all intersection points are real; the black loops are oriented counterclockwise.) Alternatively, denote $\alpha, \beta, \gamma, \delta$ by $\eta_i$, $i = 1, \ldots, 4$, numbering them consecutively according to the decreasing of the $y$-coordinate. (For example, in Figure 2 one has $\alpha = \eta_1$, $\delta = \eta_2$, $\beta = \eta_3$, $\gamma = \eta_4$.)

We always assume that $\alpha, \beta, \gamma, \delta$ are small loops about the three points of $F \cap \hat{B}_1$, numbered consecutively, whereas $\delta$ is a loop about $F \cap \hat{L}$. Thus, the position of $\delta$ in the sequence $(\alpha, \beta, \gamma, \delta)$ may change; this position is important for some relations.

![Figure 2. The basis $\alpha, \beta, \gamma, \delta$ and the loops $\xi_i$](image_url)

The braid group $B_4$ acts on $\pi_F$: we denote by $\sigma_1, \sigma_2, \sigma_3$ the standard generators of $B_4$ and consider the right action defined by $\sigma_i : \eta_i \mapsto \eta_i \eta_i \eta_i^{-1}, \eta_{i+1} \mapsto \eta_i$.

Let $F_1, \ldots, F_k$ be the singular fibers of $\hat{B}_1 + \hat{L}$. (Recall that singular are the fiber $\{x = 0\}$ through $P_0$, the vertical tangents through $P_1$ and $P_2$, and the fibers through the points of intersection of $B_1$ and $\hat{L}$.) Let $\xi_1, \ldots, \xi_k$ be a basis for the group $\pi_1(S \setminus (\bigcup F_i \cup \{x = \infty\}), P)$ similar to that shown in Figure 2, left; each $\xi_i$ is a small loop about $S \cap F_i$ connected to $P$ by a segment, circumventing the interfering fibers in the counterclockwise direction. (In the figures, we consider the section $\hat{L}$ given by (2.3.2); necessary modifications for the other cases are discussed below.) The bold grey lines in the figures represent the real parts $\text{Fix conj}_\xi$, $\epsilon = 1$.

For each $i$, let $m_i \in B_4$ be the braid monodromy along $\xi_i$, i.e., the automorphism of $\pi_F$ obtained by dragging $F$ along $\xi_i$ while keeping the base point on $\xi_i$. Then, the Zariski–van Kampen theorem [15] states that

$$\pi_1 = \langle \alpha, \beta, \gamma, \delta \mid m_i = \text{id}, i = 1, \ldots, k; (\eta_1 \eta_2 \eta_3 \eta_4)^2 = 1 \rangle.$$ (3.1.1)

Here, each braid relation $m_i = \text{id}$ should be understood as a quadruple of relations $m_i(\alpha) = \alpha$, $m_i(\beta) = \beta$, $m_i(\gamma) = \gamma$, $m_i(\delta) = \delta$; the precise form of the relation at infinity $(\eta_1 \eta_2 \eta_3 \eta_4)^2 = 1$ depends on the order of the generators.

Now, the passage to the group $\pi_1 := \pi_1(\mathbb{P}^2 \setminus B)$ is straightforward (see [7] for details): one has $\pi_1 = \text{Ker}[\kappa : \pi_1(\mathbb{P}^2 \setminus B) \to \mathbb{Z}_2]$, where $\kappa : \alpha, \beta, \gamma \mapsto 0$ and $\kappa : \delta \mapsto 1$. In terms of the presentations, we have the following statement.
3.1.2. Lemma. If \( \pi_1 \) is given by \( \langle \alpha, \beta, \gamma, \delta \mid R_j = 1, \ j = 1, \ldots, s \rangle \), then

\[
\pi_1 = \langle \alpha, \beta, \beta, \gamma, \delta \mid R_j' = R_j = 1, \ j = 1, \ldots, s \rangle,
\]

where bar stands for the conjugation by \( \delta \), \( \bar{w} = \delta w \delta \), and \( R_j' \) is obtained from \( R_j \), \( j = 1, \ldots, s \) by letting \( \delta^2 = 1 \) and expressing the result in terms of \( \alpha, \beta, \ldots \). \( \square \)

3.1.3. Remark. Note that \( \bar{w} = \delta w \delta \) is an involutive automorphism of \( \pi_1 \). Hence, whenever a relation \( R = 1 \) holds in \( \pi_1 \), the relation \( \bar{R} = 1 \) also holds.

3.2. Computing the braid monodromy. In this section, we make a few general remarks that facilitate the computation of the braid monodromy.

According to [7], in the presence of the relation at infinity, (any) one of the braid relations can be ignored. We will ignore the relation arising from the monodromy around the cusp \( P_0 \).

Since the curves \( \overline{B}_i \) and \( \overline{L} \), the initial fiber \( F \), and the base point \( P \) are all chosen conj-real, the conjugation \( \text{conj} \) induces an automorphism \( \text{conj} : \pi_1 \rightarrow \pi_1 \). Hence, for each pair \( F_k \) of conjugate singular fibers, it suffices to compute the monodromy \( m_+ \) about \( F_k \); the relations for \( F_- \) are obtained from those for \( F_- \) by applying \( \text{conj} \). The images under \( \text{conj} \) of the generators \( \alpha, \beta, \gamma, \delta \) are shown in Figure 2, left: the loops are oriented in the clockwise direction and connected to \( P \) by the dotted grey paths. Thus, the action of \( \text{conj} \) is as follows:

\[
\begin{align*}
\eta_1 &\mapsto \eta_1^{-1}, \\
\eta_2 &\mapsto \eta_1 \eta_2^{-1} \eta_1^{-1}, \\
\eta_3 &\mapsto (\eta_1 \eta_2 \eta_3)^{-1} (\eta_1 \eta_2)^{-1}, \\
\eta_4 &\mapsto (\eta_1 \eta_2 \eta_3 \eta_4)^{-1} (\eta_1 \eta_2 \eta_3)^{-1}.
\end{align*}
\]

Its precise form in terms of \( \alpha, \beta, \gamma, \delta \) depends on the order of the generators.

The relations arising from conj-real singular fibers are easily computed using the plots: the monodromy along a small circle about the fiber (or along a semicircle circumventing another singular fiber) is found using a local normal form of the singularity, and along a segment of the real line the four points of \( \overline{B}_1 + \overline{L} \) can be traced as all but at most two of them are real. In the computation below, we merely indicate the resulting relations. (Clearly, it does not really matter whether the interfering singular fibers are circumvented in the counterclockwise or clockwise direction; each time, we choose the more convenient one.)

The monodromy \( m_+ \) about \( P_+ \) has the form \( \sigma_3^2 m'_+ \sigma_3^{-1} \), where \( m_+ \) is the monodromy along the small loop about \( P_+ \) connected to the point over \( x = \epsilon + \tau \) by a \( \text{conj} \)-real segment \( L_+ \). (For \( m'_+ \), we choose the generators \( \alpha', \beta', \gamma' \) in the fiber \( F' \) over \( x = \epsilon + \tau \) similar to Figure 2 and take for \( \delta' \) the image of \( \delta \) under the monodromy along the arc \( x = \tau \exp(it), t \in [0, 2\pi/3] \). Note that the point \( F' \cap \overline{L} \) has positive imaginary part, i.e., in Figure 2 it would be located to the right from \( F'_+ \).) Now, \( m'_+ \) is found similar to the monodromy about \( P_1 \), using a plot of the \( \text{conj} \)-real part of \( \overline{B} \), which looks exactly the same as its conj-real part. However, when computing the braid along \( L_+ \), one should take into account the points of intersection of \( \overline{L} \) and the \( \text{conj} \)-real part \( (\epsilon + \mathbb{R}, \mathbb{R}) \) of \( \Sigma_2 \).

The relations for the conjugate point \( P_- \) are obtained from those for \( P_+ \) by applying \( \text{conj} \).
3.3. The set of singularities $\mathbf{(A_1^7)} \oplus \mathbf{A_2}$. Take for $\bar{L}$ the section given by (2.3.2). The curve and the section are plotted in Figure 3.

The basis $(\eta_1, \eta_2, \eta_3, \eta_4) = (\alpha, \delta, \beta, \gamma)$ is as shown in Figure 2, and the relations are

\[
\begin{align*}
(\beta \gamma)^{-1} \gamma (\beta \gamma) &= \alpha & \text{(the vertical tangent through $P_+$)}, \\
(\delta \beta \gamma \beta) \gamma (\delta \beta \gamma \beta)^{-1} &= \alpha & \text{(the vertical tangent through $P_-$)}, \\
(\alpha \delta)^3 &= (\delta \alpha)^3 & \text{(the inflection tangency)}, \\
(\delta \alpha \delta)^{-1} \alpha (\delta \alpha \delta) &= \beta & \text{(the vertical tangent through $P_1$)}, \\
[(\alpha \delta)^{-1} \delta (\alpha \delta)] \beta \gamma \beta^{-1} &= 1 & \text{(the transversal intersection)}, \\
(\alpha \delta \beta \gamma)^2 &= 1 & \text{(the relation at infinity)}.
\end{align*}
\]

(The monodromy $m_+$ about $P_+$ is computed as explained in Section 3.2; since $\bar{L}$ has no conic-real points over $L_+$, see Section 2.3, the result is $\sigma_3^2 \sigma_2 \sigma_1 \sigma_2^{-1} \sigma_3^{-3}$.) Using Lemma 3.1.2, we obtain the following relations for $\pi_1$:

\[
\begin{align*}
(3.3.1) & \quad \gamma \beta \gamma = \beta \gamma \alpha, \quad \gamma \beta \gamma = \beta \gamma \alpha, \\
(3.3.2) & \quad \beta \gamma \beta \gamma = \alpha \beta \gamma \beta, \quad \beta \gamma \beta \gamma = \alpha \beta \gamma \beta, \\
(3.3.3) & \quad \alpha \beta \alpha = \alpha \beta \alpha, \\
(3.3.4) & \quad \alpha^{-1} \alpha \beta = \beta, \quad \alpha^{-1} \alpha \beta = \beta, \\
(3.3.5) & \quad (\alpha \beta ) \gamma (\alpha \beta )^{-1} = (\alpha \beta ) \gamma (\alpha \beta )^{-1}, \\
(3.3.6) & \quad \alpha \beta \gamma \alpha \beta \gamma = 1.
\end{align*}
\]

From (3.3.4) it follows that $\alpha \beta = \alpha \beta$ and $\alpha \beta = \alpha \beta$. Substituting these expressions to (3.3.5), we obtain $\alpha \beta = \alpha \beta$ or, replacing $\alpha \beta$ with $\alpha \beta$.
from (3.3.3), α⁻¹γα = a⁻¹γa. Thus, introducing γ₁ = a⁻¹γa instead of γ, we obtain

γ₁ = γ₁.

Use (3.3.4) and (3.3.3) again to get α⁻¹βα = a and a⁻¹βa = a. Then, the conjugation of the first and second relations (3.3.1) by α and a, respectively, turns them into

(3.3.7)

γ₁aγ₁ = aγ₁a

and

γ₁αγ₁ = αγ₁a.

Similarly, relations (3.3.2) turn into

σ₁ασ₁γ₁ = α⁻¹(ασ₁α)γ₁α

and

αγ₁αγ₁ = a⁻¹(αaαa)αγ₁α;

using (3.3.3), they simplify to γ₁aγ₁ = αγ₁α and γ₁αγ₁ = aγ₁α. Comparing these expressions to (3.3.7), one concludes that α = a. Hence, also β = a and γ = a. And the map α, α, β, β → σ₁, γ, γ → σ₂ establishes an isomorphism

π₁(B² \ B) = B₃.

(Relation (3.3.6), which turns into (σ₁σ₂)² = 1, is equivalent to (σ₁σ₂)² = 1 in B₃.)

3.4. The set of singularities (2A₈) ⊕ A₃. Take for L the section given by (2.3.4). The curve and the section are shown in Figure 4.

![Figure 4. The set of singularities (2A₈) ⊕ A₃](image)

The singular fibers of B₁ + L and the basis for π₁(S \ (⋃Fᵢ ∪ {x = ∞})) are shown in Figure 5, where Q₁ are the two points of transversal intersection of B₁ and L, see Section 2.3. In the basis (η₁, η₂, η₃, η₄) = (δ, α, β, γ) for the group πF, the relations are

(βγ)⁻¹γ(βγ) = (δα)⁻¹α(δα)  (the vertical tangent through P⁺),
\((\beta\gamma\beta)(\delta\gamma\beta)^{-1} = \delta\alpha\delta^{-1}\) (the vertical tangent through \(P_\pm\)),
\(\alpha = \beta\) (the vertical tangent through \(P_0\)),
\((\alpha\delta)^4 = (\delta\alpha)^4\) (the quadruple intersection point),
\((\delta\alpha\beta\gamma)^2 = 1\) (the relation at infinity).

The monodromy \(m_+\) about \(P_+\) is found as explained in Section 3.2. This time, \(\bar{L}\) does have a conj\(_-\)-real point over \(L_+\), see Section 2.3, which is located between the two upper branches of \(B_1\). Hence, \(m_+ = \sigma_3^3\sigma_1^3\sigma_2^2\sigma_1^{-2}\sigma_3^{-3}\).

![Diagram](figure5.png)

**Figure 5.** The basis in \(\pi_1(S \setminus (\bigcup F_i \cup \{x = \infty\}))\)

To compute the monodromy \(n_+\) along the loop \(\zeta_+\) about \(Q_+\), observe that \(\zeta_+\) is homotopic to the loop \(\xi\) 'surrounding' the upper half-plane \(\text{Im } x > 0\) (the dotted black loop in Figure 5). More precisely, the loop \(\xi\) is composed of a large semicircle \(x = r \exp(it)\), \(t \in [0, \pi]\), \(r \gg 0\), and real segment \([-r, r]\) circumventing the real singular fibers in the *clockwise* direction. The braid over the real segment is found using local normal forms of the singularities and the plot of the real part of the curve; it is shown in Figure 6. The braid over the imaginary semicircle is the element \(\Delta^2 \in \mathbb{B}_4\) corresponding to one full turn. (Indeed, when \(x\) tends to infinity, \(\bar{B} + \bar{L}\) has four quadratic branches with pairwise distinct leading coefficients.) Hence, the monodromy \(m\) along \(\xi\) is

\[m = (\sigma_2^{-1})(\sigma_3^{-1}\sigma_2)\Delta^2(\sigma_4^{-1})(\sigma_3^{-4}),\]

and \(n_+ = mm_+^{-1}\).

![Diagram](figure6.png)

**Figure 6.** The braid \(m_+\) (to be closed by \(\Delta^2\))
Equate \( n_+ (\delta) = \delta \), we obtain the relation
\[
\delta \alpha^{-1} \beta \gamma^{-1} \delta \alpha^{-1} \beta \gamma^{-1} \delta^{-1} = \delta,
\]
resulting from the monodromy about \( Q_+ \). The relation from \( Q_- \) is obtained by applying \( \text{conj} \) \( \alpha \). Simplifying both relations, we get
\[
\begin{align*}
(3.4.1) \quad & [\alpha^{-1} \delta \alpha, \gamma^{-1} \beta \gamma] = 1, \\
(3.4.2) \quad & [\beta^{-1} \delta \beta, \gamma \beta \gamma^{-1}] = 1.
\end{align*}
\]
Eliminate \( \alpha \) using the relation \( \alpha = \beta \), substitute \( \beta^{-1} \delta \beta = \delta_1 \), let \( \delta_1^2 = 1 \), and pass to the generators \( \beta, \gamma \) and \( \bar{\beta} = \delta_1^{-1} \delta_1 \), \( \bar{\gamma} = \delta_1^{-1} \gamma \delta_1 \), cf. Lemma 3.1.2. We obtain the following set of relations for \( \pi_1 \):
\[
\begin{align*}
(3.4.3) \quad & \gamma \bar{\beta} \gamma = \beta \gamma \bar{\beta}, \quad \gamma \bar{\gamma} \gamma = \beta \gamma \bar{\gamma}, \\
(3.4.4) \quad & \gamma \bar{\beta} \gamma = \beta \gamma \bar{\beta}, \quad \gamma \bar{\gamma} \gamma = \beta \gamma \bar{\gamma}, \\
(3.4.5) \quad & (\beta \bar{\beta})^2 = (\beta \gamma \bar{\gamma})^2, \\
(3.4.6) \quad & \gamma \bar{\beta} \gamma = \beta \gamma \bar{\beta}, \quad \gamma \bar{\gamma} \gamma = \beta \gamma \bar{\gamma}, \\
(3.4.7) \quad & \gamma \bar{\beta} \gamma = \beta \gamma \bar{\beta}, \quad \gamma \bar{\gamma} \gamma = \beta \gamma \bar{\gamma}, \\
(3.4.8) \quad & \beta \gamma \beta \bar{\gamma} \beta = 1.
\end{align*}
\]
Here, relation (3.4.1) turns into \( \gamma^{-1} \beta \gamma = \bar{\gamma}^{-1} \beta \bar{\gamma} \); in the presence of (3.4.3) it is equivalent to (3.4.6). Similarly, (3.4.2) turns into \( \gamma \beta \gamma^{-1} = \bar{\gamma} \beta \bar{\gamma}^{-1} \), which is equivalent to (3.4.7) in the presence of (3.4.4).

To simplify the group, consider the generators \( u = \beta \gamma \beta \) and \( v = \gamma \beta \), so that \( \beta = uv^{-1} \) and \( \gamma = \bar{v}^2 u^{-1} \). Then \( \bar{u} = u^{-1} \) (from (3.4.8)) and \( \bar{v} = u^2 v^{-2} \) (from the first relation in (3.4.7)). Since the automorphism \( w \mapsto \bar{w} \) is an involution, one must have \( v = \bar{u}^2 \bar{v}^{-2} \), \( \beta \bar{\beta} = \beta \gamma \bar{\gamma} \bar{\beta} = \beta \gamma \bar{\gamma}^{-1} \).
\[
(3.4.9) \quad u^2 v u^2 = \bar{v}^2 u^{-2} \bar{v}^2.
\]
Equate the right hand sides of the first equations in (3.4.3) and (3.4.4) to obtain
\[
uvu^{-2}v^2u^{-2} = u^{-1}v^2u^{-2}v, \text{ or } [v, u^{-2}v^2u^{-2}] = 1.
\]
Using (3.4.9), we get \( [v, u^2] = 1 \); hence \( v^2 = u^6 \) and \( [v, u^3] = 1 \). Then the first relation in (3.4.3) simplifies to \( u^2 = 1 \); hence also \( v^2 = 1 \), \( \bar{u} = u \), and \( \bar{v} = v \). Thus, \( \beta = \beta, \gamma = \gamma \), and the map \( \beta, \gamma \mapsto \sigma_1 \), \( \gamma, \bar{\gamma} \mapsto \sigma_2 \) establishes an isomorphism
\[
\pi_1 (\mathbb{CP}^2 \setminus B) = \mathbb{B}_3.
\]

3.5. Perturbations of singular points. Consider an isolated singular point \( P \) of a plane curve \( B \), pick a Milnor ball \( U \) about \( P \), and consider a perturbation \( B_t \), \( t \in [0, 1] \), of \( B = B_0 \) transversal to \( \partial U \). Let \( B' = B_1 \). We are interested in the perturbation epimorphism \( \pi_1 (U \setminus B) \to \pi_1 (U \setminus B') \), cf. [25].

A perturbation \( B \) to \( B' \) is called maximal if the total Milnor number of \( B' \cap U \) equals \( \mu (\ell) - 1 \). A perturbation is called irreducible if the normalization of \( B' \cap U \) is connected (equivalently, if the abelianization of \( \pi_1 (U \setminus B') \) is cyclic). If \( P \) is simple, any irreducible perturbation factors through a maximal irreducible one.
Let $P$ be of type $A_{3k-1}$ or $E_6$. Then the ball $U$ admits a regular $S_3$-covering ramified at $B$. Let $\phi : \pi_1(U \setminus B) \to \mathbb{Z}_3$ be the corresponding epimorphism of the fundamental group. A perturbation $B'$ of $P$ is said to be of \textit{torus type} if $\phi$ factors through the perturbation epimorphism above. From the results of [5] it follows that, if $B$ is a sextic of torus type and $P$ is an inner singularity of $B$, then $B'$ is still of torus type if and only if the perturbation is of torus type.

According to E. Looijenga [16], the deformation classes (in the obvious sense) of perturbations of a simple singularity $P$ are enumerated by the induced subgraphs of the Dynkin diagram of $P$ (up to a certain equivalence, which is not important here). In the statements and proofs below, we merely indicate the result of the enumeration.

3.5.1. Lemma. The maximal irreducible perturbation of a type $A_{11}$ singular point are $A_5 \oplus A_2$ (of torus type) and $A_{10} \oplus A_6 \oplus A_4$ (not of torus type). In the former case, the group $\pi_1(U \setminus B')$ equals $\mathbb{Z}_3$; in the latter case, it is cyclic.

3.5.2. Lemma. The maximal irreducible perturbation of a type $A_5$ singular point are $2A_2$ (of torus type) and $A_4$ (not of torus type). In the former case, the group $\pi_1(U \setminus B')$ equals $\mathbb{Z}_3$; in the latter case, it is cyclic.

3.5.3. Lemma. The maximal irreducible perturbation of a type $A_7$ singular point are $A_6$ and $A_2 \oplus A_2$. For these perturbations, the group $\pi_1(U \setminus B')$ is cyclic.

Proof of Lemmas 3.5.1–3.5.3. All statements are a well known property of type $A$ singular points: any perturbation of a type $A_p$ singular point has the set of singularities $\bigoplus A_{p_i}$ with $d = (p + 1) - \sum (p_i + 1) \geq 0$, and the group $\pi_1(U \setminus B')$ is given by $\langle \alpha, \beta \mid \sigma^s \alpha = \alpha, \sigma^s \beta = \beta \rangle$, where $\sigma$ is the standard generator of the braid group $B_2$ acting on $\langle \alpha, \beta \rangle$ and $s = 1$ if $d > 0$ or $s$ = g. c. d. $(p_i + 1)$ if $d = 0$.

A perturbation is reducible if and only if $s$ above is even; a perturbation is of torus type if and only if $s = 0 \mod 3$. \hfill \qed

3.5.4. Lemma. The only maximal irreducible perturbation of a type $D_5$ singular point is $A_4$. For this perturbation, the group $\pi_1(U \setminus B')$ is cyclic.

Proof. The perturbation $B_t$ can be realized by a family $C_t \subset \mathbb{C}^2$ of affine quartics with a point of quadruple intersection with the line at infinity, so that $(U, B_t) \cong (\mathbb{C}^2, C_t)$ for each $t \in [0, 1]$. For a quartic $C_1$ with a type $A_4$ singular point, one has $\pi_1(\mathbb{C}^2 \setminus C_1) = \mathbb{Z}$, see [2]. \hfill \qed

3.5.5. Lemma. For any nontrivial perturbation of a type $D_4$ singular point, the group $\pi_1(U \setminus B')$ is abelian.

Proof. Any perturbation $B_t$ of a type $D_4$ singular point can be realized by a family $C_t \subset \mathbb{C}^2$ of affine cubics transversal to the line at infinity, so that $(U, B_t) \cong (\mathbb{C}^2, C_t)$ for each $t \in [0, 1]$. Unless $C_t$ is a triple of lines passing through a single point, the group $\pi_1(\mathbb{C}^2 \setminus C_t)$ is abelian. \hfill \qed

3.5.6. Lemma. The maximal irreducible perturbations of a type $E_7$ singular point are $E_6$, $A_6$, and $A_4 \oplus A_2$. For the perturbation $A_4 \oplus A_2$, one has $\pi_1(U \setminus B') = \mathbb{Z} \times \text{SL}(2, \mathbb{F}_5)$; for other irreducible perturbations, the group $\pi_1(U \setminus B')$ is cyclic.

Proof. Any perturbation $B_t$ of a type $E_7$ singular point can be realized by a family $C_t \subset \mathbb{C}^2$ of affine quartics intersection tangent to the line at infinity (see, e.g., [1]), so
that $(U, B_t) \cong (\mathbb{C}^2, C_t)$ for each $t \in [0, 1]$. The groups $\pi_1(\mathbb{C}^2 \setminus C_t)$ for such quartics are found in [2].

We need an explicit description of the epimorphism $\pi_1(U \setminus B) \to \pi_1(U \setminus B')$ for the perturbation $\mathbb{E}_7 \to A_4 \cong A_2$. Consider the isotrivial trigonal curve $\tilde{B} \subset \Sigma_2$ given by $y^3 + x^3 y = 0$. It has two singular fibers: a fiber of type $\mathbb{E}_7$ at $P = (0, 0)$ and a fiber of type $\tilde{A}_4^0$ over $x = \infty$. Let $\tilde{U}$ be the affine part of $\Sigma_2$ (the complement of the exceptional section $E$ and the fiber over $x = \infty$). Then the pair $(\tilde{U}, \tilde{B})$ is diffeomorphic to the pair $(U, B)$ above, and the perturbation can be realized by deforming $\tilde{B}$ to a maximal trigonal curve $\tilde{B}'$ with singular fibers of types $\tilde{A}_4$, $\tilde{A}_2$, $\tilde{A}_4^0$, and $\tilde{A}_4^1$ (keeping the last one at infinity).

**Figure 7.** The skeleton of $\tilde{B}'$.

The skeleton of the perturbed curve $\tilde{B}'$ is shown in Figure 7. It follows that $\tilde{B}'$ and all its real fibers can be chosen real, and one can use the skeleton to sketch the real part of $\tilde{B}'$ and compute the braid monodromy. (Alternatively, one can use the description of the braid monodromy in terms of the skeleton given in [4].) As a result, in the standard generators $\alpha$, $\beta$, $\gamma$, cf. Figure 2, in the fiber over $x < 0$ (in which both $\tilde{B}$ and $\tilde{B}'$ have three real points), the relations for $\pi_1(\tilde{U} \setminus \tilde{B}')$ are

$$\alpha \beta \alpha = \beta \alpha \beta, \quad \alpha \gamma \alpha = \gamma \alpha \beta, \quad \gamma \alpha \gamma = \beta \gamma \alpha.$$  

### 3.6. Perturbations of sextics of torus type.

Here, we state a few simple lemmas about irreducible plane sextics of torus type with the fundamental group $\pi_1(\mathbb{P}^2 \setminus B) = \mathbb{Z}_3$. (Note that, in fact, any sextic whose group is $\mathbb{Z}_3$ is irreducible and then, due to [5], it is of torus type.)

#### 3.6.1. Lemma. Let $B$ be an irreducible plane sextic of torus type. Then any epimorphism $\phi: \mathbb{Z}_3 \to \pi_1(\mathbb{P}^2 \setminus B)$ factors through an isomorphism $\mathbb{Z}_3 = \pi_1(\mathbb{P}^2 \setminus B)$.

**Proof.** Recall that $(\sigma_1 \sigma_2)^3 \in \mathbb{Z}_3$ is a central element whose image in the abelianization $\mathbb{Z}_3/[\mathbb{Z}_3, \mathbb{Z}_3] = \mathbb{Z}$ is 6. Since the abelianization of $\pi_1(\mathbb{P}^2 \setminus B)$ is $\mathbb{Z}$, one has $(\sigma_1 \sigma_2)^3 \in \text{Ker} \phi$ and $\phi$ factors to an epimorphism $\mathbb{Z}_3 \to \pi_1(\mathbb{P}^2 \setminus B)$. On the other hand, there is an epimorphism $\pi_1(\mathbb{P}^2 \setminus B') \to \mathbb{Z}_3$ induced by the perturbation of $B$ to Zariski's six cuspidal sextic, see [25]. Since the group $\mathbb{Z}_3 = \text{PSL}(2, \mathbb{Z})$ is obviously residually finite, hence Hopfian, both epimorphisms are isomorphisms.

#### 3.6.2. Corollary. Let $B$ be a sextic of torus type, $\pi_1(\mathbb{P}^2 \setminus B) = \mathbb{Z}_3$, and let $B'$ be a perturbation of $B$ which is also of torus type. Then $\pi_1(\mathbb{P}^2 \setminus B') = \mathbb{Z}_3$.

#### 3.6.3. Lemma. Let $B$ be a sextic of torus type with $\pi_1(\mathbb{P}^2 \setminus B) = \mathbb{Z}_3$, and let $U$ be a Milnor ball about an inner singular point $P$ of $B$. Then the inclusion homomorphism $\pi_1(U \setminus B) \to \pi_1(\mathbb{P}^2 \setminus B)$ is onto.

**Proof.** Consider a perturbation $B_t$, $t \in [0, 1]$, of $B = B_0$ to a six cuspidal sextic $B' = B_1$, transversal to $\partial U$. Pick a cusp $P' \in U$ of $B'$, consider a Milnor ball $U'$
about $P'$, and let $i: U' \smallsetminus B' \hookrightarrow U \smallsetminus B'$ and $j: U \smallsetminus B' \hookrightarrow \mathbb{P}^2 \smallsetminus B'$ be the inclusions. The homomorphism $(j \circ i)_*: \pi_1(U' \smallsetminus B') \to \pi_1(\mathbb{P}^2 \smallsetminus B')$ is onto; see [25]; hence, so is $j_*$. On the other hand, the perturbation $B \to B'$ induces an epimorphism $\pi_1(U \smallsetminus B) \to \pi_1(U \smallsetminus B')$ and an isomorphism $\pi_1(\mathbb{P}^2 \smallsetminus B) = \pi_1(\mathbb{P}^2 \smallsetminus B')$, see Corollary 3.6.2; hence, the inclusion homomorphism $\pi_1(U \smallsetminus B) \to \pi_1(\mathbb{P}^2 \smallsetminus B)$ is onto. □

3.6.4. Lemma. Let $B$ be a sextic of torus type with simple singularities and with $\pi_1(\mathbb{P}^2 \smallsetminus B) = \mathbb{Z}_3$, and let $B'$ be a perturbation of $B$ which is not of torus type. Then $\pi_1(\mathbb{P}^2 \smallsetminus B') = \mathbb{Z}_6$.

Proof. Since $B'$ is not of torus type, there is an inner singular point $P$ of $B$ that undergoes a perturbation not of torus type. Let $U$ be a Milnor ball about $P$. If $P$ is of type $E_6$, the group $\pi_1(U \smallsetminus B')$ is abelian, see [10], and the statement follows from Lemma 3.6.3. Assume that $P$ is of type $A_{3k-1}$. Then

$$\pi_1(U \smallsetminus B) = \langle \alpha, \beta | \sigma^{3s} = \text{id} \rangle \quad \text{and} \quad \pi_1(U \smallsetminus B') = \langle \alpha, \beta | \sigma^s = \text{id} \rangle$$

for some $s \neq 0 \mod 3$, see the proof of Lemmas 3.5.1–3.5.3. On the other hand, in the group $\pi_1(\mathbb{P}^2 \smallsetminus B) = \mathbb{Z}_3$, the generators $\alpha, \beta$ are subject to the braid relation $\sigma^3 = \text{id}$. (From the proof of Lemma 3.6.3, it follows that $\alpha, \beta$ are taken to the standard generators $\sigma_1, \sigma_2 \in \mathbb{Z}_3$. Hence, after the perturbation, one has a relation $\sigma = \text{id}$, i.e., $\alpha = \beta$ in $\pi_1(\mathbb{P}^2 \smallsetminus B')$, and Lemma 3.6.3 applies. □

Proof of Theorem 1.1.3. Due to the results of Sections 3.3 and 3.4, Corollary 3.6.2 implies that, for any sextic $B$ of torus type obtained by a perturbation from an irreducible sextic with the set of singularities $(A_{17}) \oplus A_2$ or $(2A_8) \oplus A_3$, one has $\pi_1(\mathbb{P}^2 \smallsetminus B) = \mathbb{Z}_3$. In particular, this statement covers all curves listed in Theorem 1.1.3, as their moduli spaces are connected, see Theorem 1.1.1. □

Now, consider a perturbation $B'$ of $B$ that is not of torus type. The extremal sets of singularities obtained in this way are

$$A_{10} \oplus A_2, \quad A_{15} \oplus A_2 \oplus A_1, \quad A_{13} \oplus A_3 \oplus A_2,$$

$$A_{12} \oplus A_4 \oplus A_2, \quad A_{10} \oplus A_4 \oplus A_2, \quad A_9 \oplus A_7 \oplus A_2,$$

$$A_8 \oplus A_7 \oplus A_3, \quad A_8 \oplus A_6 \oplus A_3 \oplus A_1, \quad A_8 \oplus A_4 \oplus 2A_3.$$

Due to Lemma 3.6.4, each of these sets of singularities is realized by a sextic whose fundamental group is cyclic.

4. REDUCIBLE CURVES OF TORUS TYPE

Now, we consider the maximal reducible sextics of torus type of the form $B = \text{Dbl}_L B_2$, where $B_2$ is the trigonal curve as in 2.5. The computation of the group $\pi_1(\mathbb{P}^2 \smallsetminus B)$ follows the outline in Sections 3.1 and 3.2, with an additional simplification due to the fact that the singular fibers of $B_2 + L$ are all real; we systematically ignore the relation from the singular fiber at infinity.

Instead of simplifying the obtained presentations for $\pi_1(\mathbb{P}^2 \smallsetminus B)$, we perturb $B$ to an irreducible sextic $B'$ and use Lemmas 3.5.1–3.5.6 to compute $\pi_1(\mathbb{P}^2 \smallsetminus B')$. If $B'$ is of torus type, we only prove that there is an epimorphism $\mathbb{Z}_3 \to \pi_1(\mathbb{P}^2 \smallsetminus B)$; Lemma 3.6.1 implies that it is an isomorphism. (Similarly, if $B'$ is not of torus type,
we only prove that the group is abelian.) Furthermore, we only consider maximal irreducible perturbations; as the groups obtained are $\mathbb{B}_3$ or $\mathbb{Z}_6$, the results extend to other perturbations using Corollary 3.6.2 and Lemma 3.6.4.

Here and in §6, without further references, the perturbations are constructed using Proposition 5.1.1 in [8], by perturbing the singular points independently.

Figure 8. The set of singularities $(A_{11} \oplus 2A_2) \oplus A_2 \oplus 2A_1$

4.1. The set of singularities $(A_{11} \oplus 2A_2) \oplus A_2 \oplus 2A_1$. Take for $\hat{L}$ the section given by (2.5.1), see Figure 8 (where the point $R_1$ of transversal intersection of $\hat{L}'$ and the lower branch of $B_2'$ is missing), and choose the generators $(\eta_1, \eta_2, \eta_3, \eta_4) = (\alpha, \beta, \delta, \gamma)$ in a real fiber $F$ just to the left from $R_2$ (e.g., over $x = 0.2$). The relations for $\pi_1$ are:

\[
\begin{align*}
\delta(\alpha\beta)^3 &= (\beta\alpha\beta)(\alpha\beta) \\
[\delta, \alpha\beta] &= 1 \\
[(\beta\alpha\beta)^{-1}\alpha(\beta\alpha\beta), \gamma] &= 1 \\
(\gamma\delta)^3 &= (\delta\gamma)^3 \\
\beta &= (\delta\gamma\delta)(\delta\gamma\delta)^{-1} \\
[\beta^{-1}\alpha\beta, (\delta\gamma)(\delta\gamma)^{-1}] &= 1 \\
(\alpha\beta\delta\gamma)^2 &= 1
\end{align*}
\]

(the fiber through $R_5$),

(the fiber through $R_6$),

(the fiber through $R_1$),

(the fiber through $Q_6$),

(the vertical tangent),

(the fiber through $Q_1$),

(the relation at infinity).

Passing to the generators $\alpha, \alpha, \beta, \beta, \gamma, \gamma$, see Lemma 3.1.2, we obtain the following set of relations for $\pi_1(\mathbb{P}^2 \setminus B)$, where $B$ is a reducible sextic of torus type with the set of singularities $(A_{11} \oplus 2A_2) \oplus A_2 \oplus 2A_1$:

\[
\begin{align*}
(\alpha\beta)^3 &= \tilde{\beta}\tilde{\alpha}\tilde{\beta}\tilde{\alpha}, \\
(\alpha\beta)^3 &= \beta\alpha\beta\tilde{\alpha}\tilde{\beta}, \\
\alpha\beta &= \tilde{\alpha}\tilde{\beta},
\end{align*}
\]
\[(4.1.3)\] \( ([\beta \alpha \beta]^{-1} \alpha (\beta \alpha \beta), \gamma] = 1, \quad (\tilde{\beta} \tilde{\alpha} \tilde{\beta}]^{-1} \tilde{\alpha} (\tilde{\beta} \tilde{\alpha} \tilde{\beta}, \gamma] = 1, \]

\[(4.1.4)\] \( \gamma \tilde{\gamma} = \tilde{\gamma} \gamma, \)

\[(4.1.5)\] \( \beta = \tilde{\gamma} \gamma^{-1}, \quad \tilde{\beta} = \gamma \tilde{\gamma} \gamma^{-1} \)

\[(4.1.6)\] \( (\beta \gamma)^{-1} \tilde{\alpha} \tilde{\beta} \gamma = (\tilde{\beta} \gamma)^{-1} \alpha \beta \gamma, \)

\[(4.1.7)\] \( \alpha \tilde{\beta} \gamma \tilde{\alpha} \beta \gamma = 1. \)

In the presence of (4.1.1) and (4.1.2), relations (4.1.3) simplify to

\[(4.1.8)\] \( ([\tilde{\alpha} \tilde{\beta}] \tilde{\alpha} (\tilde{\alpha} \tilde{\beta}]^{-1}, \tilde{\gamma}] = 1, \quad ([\alpha \beta] \alpha (\alpha \beta]^{-1}, \gamma] = 1. \)

Consider the perturbation \( A_{11} \rightarrow A_8 \oplus A_2, \) producing an irreducible sextic \( B' \) of torus type with the set of singularities

\[ (A_8 \oplus 3A_2) \oplus A_2 \oplus 2A_1. \]

This perturbation adds the braid relation \( \alpha \beta \alpha = \beta \alpha \beta. \) Then, the first relation in (4.1.1) simplifies to \( \beta \alpha \beta = \tilde{\beta} \tilde{\alpha} \tilde{\beta}; \) in view of (4.1.2), this implies that \( \beta = \beta. \) Similarly, using the second relation in (4.1.1), one obtains \( \alpha = \tilde{\alpha}. \) Furthermore, in the presence of the braid relation, one has \( (\alpha \beta) \alpha (\alpha \beta]^{-1} = \beta; \) hence, (4.1.8) implies \( [\beta, \tilde{\gamma}] = [\beta, \gamma] = 1 \) and (4.1.5) yields \( \gamma = \tilde{\gamma} = \beta. \) Thus, the map \( \alpha, \tilde{\alpha} \mapsto \sigma_1, \beta, \tilde{\beta}, \gamma, \tilde{\gamma} \mapsto \sigma_2 \) establishes an isomorphism \( \pi_1(P^2 \setminus B') = \tilde{\mathbb{B}}_3. \)

Now, perturb one of the nodes over \( R_1, \) producing an irreducible sextic \( B' \) of torus type with the set of singularities

\[ (A_{11} \oplus 2A_2) \oplus A_2 \oplus A_1. \]

This perturbation simplifies one of the two relations (4.1.8): for example, we can replace the first one with

\[(4.1.9)\] \( \tilde{\gamma} = (\tilde{\alpha} \tilde{\beta}) \tilde{\alpha} (\tilde{\alpha} \tilde{\beta}]^{-1}. \)

To simplify the group, introduce the generators \( u = \alpha \beta \) and \( v = \alpha \beta \alpha, \) so that \( \alpha = u^{-1}v \) and \( \beta = v^{-1}u^2. \) Then \( \tilde{u} = u \) (from (4.1.2)) and \( \tilde{v} = u^{-3}v^3 \) (from the second relation in (4.1.1)). Hence, \( \tilde{\alpha} = u^{-4}v^4, \beta = u^{-3}v^{-1}u^5, \) and the new relation (4.1.9) turns into \( \tilde{\gamma} = u^{-3}v^2; \) in view of (4.1.7), this implies \( \gamma = u^{-3}v^{-1}u^2. \) Substituting the expressions obtained to the second relation in (4.1.5), we arrive at \( u^3 = v^2; \) hence, \( \alpha = \alpha = u^{-1}v, \tilde{\beta} = \beta = \gamma = u^{-1}u^4, \) and \( \gamma = v^{-3}u^2. \) Substituting to the first relation in (4.1.5), we get \( v^2 = 1. \) Thus, also \( u^3 = 1, \) and we obtain an isomorphism \( \pi_1(P^2 \setminus B') = \tilde{\mathbb{B}}_3, \) given by \( \alpha, \tilde{\alpha} \mapsto \sigma_1 \) and \( \beta, \tilde{\beta}, \gamma, \tilde{\gamma} \mapsto \sigma_2. \)

Finally, consider a maximal irreducible perturbation of the type \( A_{11} \) singular point that is not of torus type, producing irreducible plane sextics with the sets of singularities

\[ A_{10} \oplus 3A_2 \oplus 2A_1, \quad A_6 \oplus A_4 \oplus 3A_2 \oplus 2A_1. \]

(see Lemma 3.5.1). According to Lemma 3.5.1, this perturbation introduces the additional relations \( \alpha = \tilde{\alpha} = \beta = \tilde{\beta}. \) Then, from (4.1.3) one has \( [\alpha, \gamma] = [\alpha, \tilde{\gamma}] = 1 \) and, due to (4.1.7), also \( [\gamma, \tilde{\gamma}] = 1. \) Hence, the group is abelian.
4.2. The set of singularities \((2\mathbb{A}_5 \oplus 2\mathbb{A}_2) \oplus \mathbb{D}_5\). Consider the triple \(\tilde{B}_2', \tilde{L}', \tilde{L}\) as in Section 4.1, see Figure 8, but now let \(\tilde{B} = \tilde{B}_2' + \tilde{L}\) and \(B = \text{Dbl}_{\tilde{L}}(\tilde{B}_2' + L)\): it is a reducible sextic of torus type with the set of singularities \((2\mathbb{A}_5 \oplus 2\mathbb{A}_2) \oplus \mathbb{D}_5\). The group \(\pi_1 = \pi_1(\Sigma_5 \setminus (B \cup L' \cup E))\) is found in Section 4.1. Modifying Lemma 3.1.2, let \(\alpha^2 = 1\) and pass to the generators \(\beta, \tilde{\beta}, \gamma, \tilde{\gamma}, \delta, \tilde{\delta} = \alpha \delta \alpha\). We obtain the following set of relations for the group \(\pi_1(\mathbb{P}^2 \setminus B)\):

\[
\begin{align*}
(4.2.1) & \quad \delta \tilde{\beta} \beta \tilde{\beta} = \delta \tilde{\beta} \beta \tilde{\beta}, \\
(4.2.2) & \quad \delta \beta = \delta \tilde{\beta}, \quad \delta \tilde{\beta} = \delta \tilde{\beta}, \\
(4.2.3) & \quad (\beta \tilde{\beta} \delta \gamma)(\beta \tilde{\beta} \delta \gamma)^{-1} = (\beta \tilde{\beta} \delta \gamma)(\beta \tilde{\beta} \delta \gamma)^{-1}, \\
(4.2.4) & \quad (\gamma \delta)^3 = (\delta \gamma)^3, \quad (\tilde{\gamma} \delta)^3 = (\delta \tilde{\gamma})^3, \\
(4.2.5) & \quad \beta = (\delta \tilde{\gamma} \delta \gamma)(\delta \tilde{\gamma} \delta \gamma)^{-1}, \quad \tilde{\beta} = (\delta \tilde{\gamma} \delta \gamma)(\delta \tilde{\gamma} \delta \gamma)^{-1}, \\
(4.2.6) & \quad (\beta \delta \gamma \delta \beta \gamma)(\beta \delta \gamma \delta \beta \gamma)^{-1} = (\tilde{\beta} \delta \tilde{\gamma} \delta \tilde{\beta} \gamma)^{-1}, \\
(4.2.7) & \quad \beta \tilde{\gamma} \delta \tilde{\beta} \gamma = 1.
\end{align*}
\]

(Here, (4.2.1) is simplified using (4.2.2).)

The perturbation \(\mathbb{D}_5 \mapsto \mathbb{A}_4\) produces an irreducible sextic \(B'\) of torus type with the set of singularities

\[
(2\mathbb{A}_5 \oplus 2\mathbb{A}_2) \oplus \mathbb{A}_4
\]

and introduces the relation \(\beta = \tilde{\beta} = \delta = \tilde{\delta}\), see Lemma 3.5.4. Then, due to (4.2.3), \(\gamma = \tilde{\gamma}\) and (4.2.5) simplifies to \(\beta \gamma \beta = \gamma \beta \gamma\). Hence, the map \(\beta, \tilde{\beta}, \delta, \tilde{\delta} \mapsto \sigma_1, \gamma, \tilde{\gamma} \mapsto \sigma_2\) establishes an isomorphism \(\pi_1(\mathbb{P}^2 \setminus B') = \mathbb{Z}_3\).

The perturbation \(\mathbb{A}_5 \mapsto \mathbb{A}_4\) produces an irreducible sextic \(B'\) with the set of singularities

\[
\mathbb{D}_5 \oplus \mathbb{A}_5 \oplus \mathbb{A}_4 \oplus 2\mathbb{A}_2
\]

and introduces the relation \(\delta = \gamma\), see Lemma 3.5.2. Then, due to the first relation in (4.2.5), \(\beta = \gamma\), relation (4.2.2) implies \(\delta = \gamma\) and \([\beta, \gamma] = 1\), and one has \(\beta = \gamma\) (from (4.2.1)) and \(\tilde{\gamma} = \gamma^{-1}\) (from (4.2.7)). Thus, the group is abelian.

4.3. The set of singularities \((A_{11} + 2\mathbb{A}_2) \oplus \mathbb{D}_4\). Take for \(\tilde{L}\) the section given by (2.5.3), see Figure 9 (where the point \(Q_1\) of transversal intersection of \(L\) and the upper branch of \(B_2'\) is missing). Choose the generators \((\eta_1, \eta_2, \eta_3, \eta_4) = (\alpha, \beta, \delta, \gamma)\) in a real fiber \(F\) between \(R_3\) and \(R_4\) (e.g., over \(x = 1\)). The relations are:

\[
\begin{align*}
\delta(\alpha \beta)^3 &= (\beta \alpha \beta)(\alpha \beta \alpha) \quad \text{(the fiber through } R_5), \\
[\delta, \alpha \beta] &= 1 \quad \text{(the fiber through } R_6), \\
\beta(\delta \gamma)^2 &= \gamma \delta \gamma \delta \quad \text{(the fiber through } R_1), \\
[\beta, \delta \gamma] &= 1 \quad \text{(the fiber through } R_1), \\
(\beta \alpha \beta)^{-1} \alpha(\beta \alpha \beta) = \gamma &= \gamma \quad \text{(the vertical tangent)}, \\
[\alpha, \gamma^{-1} \delta \gamma] &= 1 \quad \text{(the fiber through } Q_1), \\
(\alpha \beta \delta \gamma)^2 &= 1 \quad \text{(the relation at infinity)}.
\end{align*}
\]

Passing to the generators \(\alpha, \tilde{\alpha}, \beta, \tilde{\beta}, \gamma, \tilde{\gamma}\), see Lemma 3.1.2, we obtain the following relations for the group \(\pi_1(\mathbb{P}^2 \setminus B)\) of a reducible sextic \(B\) of torus type with the
set of singularities \((A_{11} \oplus 2A_2) \oplus D_4\):

\[
\begin{align*}
(\alpha \beta)^3 &= \beta \bar{\alpha} \bar{\beta} \alpha, \\
(\alpha \beta)^3 &= \beta \alpha \beta \bar{\beta} \alpha, \\
\alpha \beta &= \bar{\alpha} \beta, \\
\beta \bar{\gamma} &= \gamma \bar{\beta}, \\
\beta \bar{\gamma} &= \gamma \bar{\beta}, \\
(\beta \alpha \beta)^{-1} \alpha (\beta \alpha \beta) &= \bar{\gamma}, \\
(\beta \alpha \beta)^{-1} \alpha (\beta \alpha \beta) &= \gamma, \\
\alpha \gamma^{-1} \bar{\gamma} &= \gamma^{-1} \bar{\gamma} \bar{\alpha}, \\
\alpha \beta \gamma^{-1} \bar{\beta} \bar{\gamma} &= 1.
\end{align*}
\]

As above, in view of (4.3.1) and (4.3.2), relations (4.3.5) simplify to

\[
\begin{align*}
(\alpha \beta) \bar{\alpha} (\alpha \beta)^{-1} &= \bar{\gamma}, \\
(\alpha \beta) \alpha (\alpha \beta)^{-1} &= \gamma.
\end{align*}
\]

The perturbation \(A_{11} \rightarrow A_8 \oplus A_2\) produces an irreducible sextic \(B'\) of torus type with the set of singularities

\[
(A_8 \oplus 3A_2) \oplus D_4.
\]

The perturbation adds to the presentation a braid relation \(\alpha \beta \alpha = \beta \alpha \beta\). Similar to Section 4.1 (the perturbation \(A_{11} \rightarrow A_8 \oplus A_2\)), relations (4.3.1) and (4.3.2) imply that \(\alpha = \bar{\alpha}\) and \(\beta = \bar{\beta}\), and (4.3.8) turns into \(\gamma = \bar{\gamma} = \beta\). Hence, there is an isomorphism \(\pi_1(\mathbb{P}^2 \setminus B') = \mathbb{Z}_3\) given by the map \(\alpha, \bar{\alpha} \mapsto \sigma_1, \beta, \bar{\beta}, \gamma, \bar{\gamma} \mapsto \sigma_2\).

Now, perturb the type \(D_4\) point of \(B\). After the perturbation, the generators \(\beta, \bar{\beta}, \gamma, \bar{\gamma}\) pairwise commute, see Lemma 3.5.5. It follows that \(\beta = \bar{\beta}\) (from (4.3.4)), \(\alpha = \bar{\alpha}\) (from (4.3.2)), and \(\gamma = \bar{\gamma}\) (from (4.3.8)), and the presentation simplifies to

\[
\begin{align*}
\langle \alpha, \beta \mid (\alpha \beta)^3 = (\beta \alpha)^3, \ (\alpha \beta \alpha)^2 = 1 \rangle.
\end{align*}
\]
This is, indeed, the fundamental group of a reducible curve of torus type whose set of singularities is

\[(A_{11} \oplus 2A_2) \oplus 3A_1, \quad (A_{11} \oplus 2A_2) \oplus A_3, \quad \text{or} \quad (A_{11} \oplus 2A_2) \oplus 2A_4.\]

To obtain an irreducible curve with the set of singularities

\[(A_{11} \oplus 2A_2) \oplus A_3,\]

we choose the perturbation \(D_4 \hookrightarrow A_3\) so that the generators \(\beta\) and \(\gamma\) become conjugate (hence equal) in \(\pi_1(U_P \setminus B')\). (Locally, we perturb a triple of lines to a conic and a line tangent to it, and the choice of a line to be kept as a separate component is governed by the choice of a subdiagram \(A_3 \subset D_4\); any such choice can be realized by a perturbation of \(B_4\).) Then, (4.3.8) implies the braid relation \(a_2a_3 = a_3a_2\), and the map \(\alpha, \bar{\alpha} \mapsto \sigma_1, \beta, \bar{\beta}, \gamma, \bar{\gamma} \mapsto \sigma_2\) establishes an isomorphism \(\pi_1(\mathbb{P}^2 \setminus B') = \mathbb{B}_3\).

The perturbations \(A_{11} \hookrightarrow A_{10}\) or \(A_6 \oplus A_4\), see Lemma 3.5.1, produce irreducible sextics with the sets of singularities

\[D_4 \oplus A_{10} \oplus 2A_2, \quad D_4 \oplus A_6 \oplus A_4 \oplus 2A_2\]

while adding the relation \(\alpha = \bar{\alpha} = \beta = \bar{\beta}\). Then (4.3.5) implies \(\gamma = \bar{\gamma} = \alpha\), and the group is abelian.

![Figure 10](image)

**Figure 10.** The sets \((E_6 \oplus A_{11}) \oplus 2A_1\) and \((E_6 \oplus 2A_5) \oplus A_3\)

### 4.4. The set of singularities \((E_6 \oplus A_{11}) \oplus 2A_1\)

Let \(\tilde{L}\) be the section given by (2.5.4), see the solid horizontal grey line in Figure 10. (The resulting set of singularities \((E_6 \oplus A_{11}) \oplus 2A_1\) is erroneously missing in Oka [19].) Choosing the generators \((\eta_1, \eta_2, \eta_3, \eta_4) = (\alpha, \beta, \delta, \gamma)\) in a real fiber \(F\) between \(R_5\) and \(Q_1\) (e.g., over \(x = 1\)), we obtain the relations

\[[\delta, \beta] = 1 \quad \text{(the fiber through} \ Q_1).\]
\[ [\delta, \alpha\beta] = 1 \quad \text{(the fiber through } R_5) \].

(We only list the few relations needed in the sequel.) Hence, also \([\delta, \alpha] = 1\). The relation at the vertical tangent of \(B\) has the form \(\gamma = (a \text{ word in } \alpha, \beta, \delta)\); hence, we also have \([\delta, \gamma] = 1\). Thus, \(\delta\) is a central element, and a presentation for the group \(\pi_1(\Sigma_2 \setminus (B \cup \tilde{L} \cup E))\) can be obtained from the presentation in Section 4.3 by adding the relations \([\alpha, \delta] = [\beta, \delta] = [\gamma, \delta] = 1\). After eliminating \(\gamma = (\beta \alpha)^{-1} \alpha(\beta \alpha)\), we get

\[
(\alpha, \beta, \delta \mid \alpha(\beta \alpha)^3 = (\beta \alpha)^3, \; [\alpha, \delta] = [\beta, \delta] = 1, \; (\alpha \beta \alpha)^2 \delta^2 = 1).
\]

The fundamental group \(\pi_1(\mathbb{P}^2 \setminus B)\) of a reducible sextic \(B\) of torus type with the set of singularities \((E_6 \oplus A_{11}) \oplus 2A_1\) is obtained from (4.4.1) by letting \(\delta = 1\). The result is (4.3.9).

A perturbation of a node of \(B\) produces an irreducible sextic of torus type with the set of singularities

\[(E_6 \oplus A_{11}) \oplus A_1.\]

The additional relation introduced by this operation is \(\beta = \gamma\). Hence, the resulting fundamental group is \(\mathbb{B}_3\), cf. the perturbation \(D_4 \hookrightarrow A_3\) in Section 4.3.

The perturbation \(A_{11} \hookrightarrow A_8 \oplus A_2\) produces the set of singularities

\[(E_6 \oplus A_8 \oplus A_2) \oplus 2A_1.\]

The additional relation is \(\alpha \beta \alpha = \beta \alpha \beta\), and the resulting group is \(\mathbb{B}_3\).

The perturbations \(A_{11} \hookrightarrow A_{10}\) or \(A_6 \oplus A_4\) produce the sets of singularities

\[E_6 \oplus A_{10} \oplus 2A_1, \quad E_6 \oplus A_6 \oplus A_4 \oplus 2A_1,\]

while adding to (4.3.9) the relation \(\alpha = \beta\), see Lemma 3.5.1. Hence, the resulting group is abelian.

4.5. The set of singularities \((E_6 \oplus 2A_5) \oplus A_3\). Let \(\tilde{L}\) be the section given by (2.5.5), see the dotted horizontal grey line in Figure 10. Choosing the generators \((\eta_1, \eta_2, \eta_3, \eta_4) = (\alpha, \beta, \gamma, \delta)\) in a real fiber \(F\) between \(R_5\) and \(R_1\) (e.g., over \(x = 1\)), we obtain the relations

\[
\begin{align*}
(\alpha \beta)^3 &= (\beta \alpha)^3, & \text{(the fiber through } R_5), \\
(\alpha \beta)\alpha(\alpha \beta)^{-1} &= \gamma & \text{(the vertical tangent)}, \\
[\delta, \alpha \beta \alpha]^{-1} &= 1 & \text{(the fiber through } Q_1), \\
[\gamma \delta, \beta] &= [\beta \gamma \delta, \gamma] = [\beta \gamma, \delta] = 1 & \text{(the fiber through } R_1), \\
(\alpha \beta \gamma \delta)^2 &= 1 & \text{(the relation at infinity)}. 
\end{align*}
\]

(The second and the third relations were simplified using the first one.) Passing to \(\alpha, \beta, \beta, \gamma, \gamma\), see Lemma 3.1.2, gives the following relations for the group of a reducible sextic \(B\) of torus type with the set of singularities \((E_6 \oplus 2A_5) \oplus A_3\):

\[
(\alpha \beta)^3 = (\beta \alpha)^3, \quad (\bar{\alpha} \bar{\beta})^3 = (\bar{\beta} \bar{\alpha})^3,
\]
(4.5.2) \[(\alpha \beta)\alpha(\alpha \beta)^{-1} = \gamma, \quad (\alpha \beta)\beta(\alpha \beta)^{-1} = \gamma,\]
(4.5.3) \[\alpha \beta \alpha^{-1} = \bar{\alpha} \bar{\beta} \alpha^{-1},\]
(4.5.4) \[\gamma \bar{\beta} = \beta \gamma = \bar{\beta} \bar{\gamma} = \gamma \beta,\]
(4.5.5) \[\alpha \beta \gamma \bar{\beta} \bar{\gamma} = 1.\]

The perturbation \(A_5 \mapsto A_4\) of one of the type \(A_5\) singular points of \(B\) produces the set of singularities

\[E_6 \oplus A_5 \oplus A_4 \oplus A_3\]

and adds the relation \(\alpha = \beta\), see Lemma 3.5.2. Then \(\gamma = \alpha\) (from (4.5.2)), \(\bar{\beta} = \bar{\gamma}\) (from (4.5.4)), and \(\bar{\alpha} = \alpha^{-1}\) (from (4.5.5)). Hence, the group is abelian.

![Figure 11. The sets (3A_5) \oplus D_4 and (A_11 \oplus A_5) \oplus A_3](image)

4.6. The set of singularities \((3A_5) \oplus D_4\). Let \(L\) be the section given by (2.5.6), see the solid grey line in Figure 11. Choosing the generators \(\alpha, \beta, \gamma, \delta\) as in Section 4.5, we obtain the same set of relations, except that the relation at the fiber through \(R_1\) should be replaced with

\[[\beta, \gamma \delta] = 1, \quad \delta \beta \gamma \delta \gamma = \beta \gamma \delta \gamma \delta \quad \text{(the fiber through } R_1)\]

Hence, the relations for \(\pi_1(\mathbb{P}^2 \setminus B)\) are (4.5.1)–(4.5.3), (4.5.5), and the relations

(4.6.1) \[\beta \gamma = \gamma \bar{\beta}, \quad \bar{\beta} \gamma = \gamma \bar{\beta}, \quad \bar{\beta} \gamma \gamma = \beta \gamma \bar{\gamma}\]

replacing (4.5.4).

We are only interested in the perturbation \(A_5 \mapsto A_4\) of two of the three type \(A_5\) singular points of \(B\), producing the set of singularities

\[D_4 \oplus A_5 \oplus 2A_4.\]

(Since \(B\) splits into three components, we need to perturb two points to get an irreducible curve.) Assume that the points perturbed are those over \(R_5\). Then the extra relations for \(\pi_1(\mathbb{P}^2 \setminus B)\) are \(\alpha = \beta\) and \(\bar{\alpha} = \bar{\beta}\), see Lemma 3.5.2, and it is straightforward that the resulting group is abelian.
4.7. The set of singularities \((A_{11} \oplus A_5) \oplus A_3\). Take for \(\bar{L}\) be the section given by (2.5.7), see the dotted grey line in Figure 11. Choosing the generators \((\eta_1, \eta_2, \eta_3, \eta_4) = (\alpha, \beta, \delta, \gamma)\) in a real generic fiber between \(R_5\) and \(R_4\) (e.g., over \(x = 1\)), we obtain the following relations:

\[
\begin{align*}
[\beta, \delta \gamma] &= [\delta, \gamma \beta] = [\gamma, \beta \delta] = 1 \quad \text{(the fiber through } R_1), \\
[\delta, \alpha \beta] &= 1 \quad \text{(the fiber through } R_3), \\
\delta (\alpha \beta)^2 &= \beta \alpha \beta \alpha \beta \alpha \quad \text{(the fiber through } R_5), \\
(\beta \alpha \delta)^{-1} \alpha (\delta \beta \alpha) &= \gamma \quad \text{(the vertical tangent)}, \\
(\alpha \beta \delta \gamma)^2 &= 1 \quad \text{(the relation at infinity)}.
\end{align*}
\]

Passing to \(\alpha, \alpha, \beta, \beta, \gamma, \gamma\), see Lemma 3.1.2, we obtain a presentation for the group of a reducible sextic of torus type with the set of singularities \((A_{11} \oplus A_5) \oplus A_3\):

\[
\begin{align*}
(4.7.1) & \quad \beta \gamma = \gamma \beta = \gamma \beta = \beta \gamma, \\
(4.7.2) & \quad \alpha \beta = \tilde{\alpha} \beta, \\
(4.7.3) & \quad (\alpha \beta)^2 = \beta \tilde{\alpha} \beta \alpha \beta \alpha = \beta \alpha \beta \alpha \beta \alpha, \\
(4.7.4) & \quad (\beta \alpha)^{-1} \alpha (\beta \alpha) = \gamma, \quad (\beta \alpha)^{-1} \alpha (\beta \alpha) = \gamma, \\
(4.7.5) & \quad \gamma \alpha \beta \gamma \tilde{\alpha} \beta = 1.
\end{align*}
\]

The perturbation \(A_2 \hookrightarrow A_4\) produces an irreducible plane sextic with the set of singularities \(A_{11} \oplus A_4 \oplus A_3\), while adding the relations \(\alpha = \gamma^{-1} \gamma \tilde{\alpha} \gamma^{-1} \gamma = \gamma = \gamma^{-1} \gamma \gamma\), see Lemma 3.5.2, which imply \(\gamma = \tilde{\gamma} = \alpha = \tilde{\alpha}\). (Observe that the standard generators in a fiber over \(x > 0\) are \(\alpha_1 = \alpha, \beta_1 = \gamma, \delta_1 = \gamma^{-1} \delta \gamma, \gamma_1 = \beta\), and the extra relations given by Lemma 3.5.2 are \(\alpha_1 = \delta_1^{-1} \alpha_1 \delta_1 = \beta_1 = \delta_1^{-1} \beta_1 \delta_1\).) The perturbations \(A_{11} \hookrightarrow A_{10}\) or \(A_6 \oplus A_4\) produce irreducible sextics with the sets of singularities \(A_{10} \oplus A_5 \oplus A_3, \quad A_6 \oplus A_5 \oplus A_4 \oplus A_3\) and add the relations \(\alpha = \tilde{\alpha} = \beta = \tilde{\beta}\), see Lemma 3.5.1. In both cases, it is immediate that the resulting group is abelian.

5. Digression: classification of reducible sextics

The curves considered in §4 are sextics of torus type splitting into a quartic and a conic. Here, we state and indicate the proofs of a few results concerning the classification and the fundamental groups of such curves. Details will be published elsewhere. In Section 5.3, we outline the proof of Theorem 1.1.2.

5.1. The symmetry. Theorem 5.1.1 below substantiates Conjecture 4.2.3 in [9], concerning the relation between involutive stable symmetries of plane sextics and maximal trigonal curves in \(\Sigma_2\).
5.1.1. Theorem. Let $B$ be a plane sextic of torus type, with simple singularities only, splitting into
- an irreducible quartic and irreducible conic,
- an irreducible quartic and two lines, or
- three irreducible conics.

Then $B$ admits an involutive stable (in the sense of [9]) symmetry $c: \mathbb{P}^2 \to \mathbb{P}^2$, and the quotient $B/c$ is the maximal trigonal curve $\tilde{B}_2 \subset \Sigma_2$ with the set of singularities $\mathbb{A}_5 \oplus \mathbb{A}_2 \oplus \mathbb{A}_1$, see Section 2.5.

Conversely, for any section $\tilde{L}$ of $\Sigma_2$ not tangent to $\tilde{B}_2$ at its type $\mathbb{A}_5$ singular point, the double $B = \text{Div}_L \tilde{B}_2$ is a plane sextic of torus type splitting as above.

5.1.2. Remark. The condition that $\tilde{L}$ should not be tangent to $\tilde{B}_2$ at its type $\mathbb{A}_5$ singular point is necessary and sufficient for $B$ to have simple singularities only.

5.1.3. Remark. For most sextics $B$ as in Theorem 5.1.1, the group of stable symmetries of $B$ is $\mathbb{Z}_2$. Exceptions are sextics splitting into three irreducible conics: for each such sextic $B$, the group of stable symmetries of $B$ is the group $S_3$ of permutations of the components of $B$.

Proof. The proof is similar to [7], [8], and [9]. Assume that $B$ splits into a quartic $B_4$ and a conic $B_2$. It is clear that the inner singularities are two cusps $R_{c_1}$, $R_{c_2}$ of $B_4$ (which may degenerate to a single type $\mathbb{A}_5$ or $\mathbb{E}_6$ singular point $R_{\infty}$ of $B_4$) and two type $\mathbb{A}_5$ points $R_1^i$, $R_2^i$ of inflection tangency of $B_4$ and $B_2$ (which may degenerate to a single type $\mathbb{A}_{11}$ point $R_3$ of 6-fold intersection). The outer singularities are the two points $R_1^i$, $R_2^i$ of simple intersection of $B_4$ and $B_2$, which may degenerate to a single type $\mathbb{A}_3$ point $R_1$. Besides, $B_4$ may have an extra node or cusp $Q_4$, and $B_2$ may have an extra node $Q_2$ (splitting into two lines). As a further degeneration, $R_1$ may merge with $Q_4$ or $Q_2$.

Consider the minimal resolution $\tilde{X}$ of the double covering $X \to \mathbb{P}^2$ ramified at $B$. It is a $K3$-surface. Let $L = H_2(X)$, let $\Sigma_P \subset L$ be the resolution lattice of a singular point $P$ of $B$, and let $\Gamma_P$ be the Dynkin graph of $P$. Denote $\Sigma = \bigoplus_P \Sigma_P$ and $\Gamma = \bigcup_P \Gamma_P$, and consider the lattice $S = \Sigma \oplus \langle h \rangle \subset L$, where $h \in L$ is the class of the pull-back of a generic line in $\mathbb{P}^2$. One has $h^2 = 2$. Let $K$ be the image of $L = L^* \subset \text{disc} S = S^*/S$. Since $B$ is of torus type, $K$ has an element of order 3, see [3]. Besides, $K$ has an element of order 2 responsible for the splitting $B = B_4 + B_2$, see [5]. (For example, the element of order 2 is represented by $\text{class } [B_2] \in H_2(X) = L$.)

Consider an involutive symmetry $c_T: \Gamma \to \Gamma$ acting as follows: $c_T$ transposes the two points within each pair $(R_{c_1}, R_{c_2}), (R_1^i, R_2^i), (R_1^i, R_2^i)$ and acts identically on the diagram of each point $Q_4$ that does not coincide with $R_1$. If a pair of points $R_1^i, R_2^i$ merges to a single point $R_3$, then $c_T$ acts on $\Gamma_R$ by its nontrivial symmetry. (This description determines $c_T$ uniquely up to a symmetry of the diagrams of $R_{c_1}$ and $R_{c_2}$ whenever these points are separate.) Let $c_S: S \to S$ be the extension of $c_T$ identical on $h$. One can check that $c_T$ can be chosen so that $c_S$ preserves $S$ and induces the identity on $K^*/K$; hence, $c_S$ extends to an involutive automorphism $c_s: L \to L$ identical on $\Sigma^\perp$. The latter is induced by a unique involutive $c: \mathbb{P}^2 \to \mathbb{P}^2$ preserving $B$, cf. [9]. Details are left to the reader.

The fact that the quotient $B/c$ is the curve $\tilde{B}_2$ is straightforward: the quotient must have singular points of types $\mathbb{A}_5$, $\mathbb{A}_2$, and $\mathbb{A}_1$, resulting from the (pairs of)
points $R_5$, $R_\infty$, and $R_4$, respectively, and, due to [9], such a curve is unique. The converse statement is obvious. □

If $B$ splits into three conics, it has three type $A_5$ inner singular points and three outer nodes, which may merge to a single type $D_4$ singular point. An order 3 symmetry of $B$, see Remark 5.1.3, is constructed as above, starting from the order 3 symmetry $\varphi : \Gamma \to \Gamma$ transposing cyclically the three inner points and three nodes (or acting by an order three symmetry on the Dynkin graph $D_4$).

5.2. **The classification.** Using the stable symmetry and the description of special sections found in 2.5 and 2.6, one immediately obtains a deformation classification of sextics splitting as in Theorem 5.1.1.

5.2.1. **Theorem.** Let $B$ be a sextic as in Theorem 5.1.1. Then the combinatorial type of singularities of $B$ is one of those listed in [19] or $(E_6 \oplus A_{11}) \oplus 2A_1$. The equisingular moduli space of sextics as in Theorem 5.1.1 realizing each of these combinatorial types is rational; in particular, it is connected.

5.2.2. **Remark.** When referring to [19], we mean the combinatorial types marked as $B_2 + B_4$, $B_1 + B_1'$ + $B_4$, or $B_3 + B_2' + B_2''$ in Theorem 1. The set of singularities $(E_6 \oplus A_{11}) \oplus 2A_1$ (an irreducible quartic with a type $E_6$ singular point and a conic, see Section 4.4) is erroneously missing in [19].

**Proof.** As in Section 2.4, the equisingular moduli spaces $\mathcal{M}(\Sigma)$ of sextics splitting as in Theorem 5.1.1 and possessing a given set of singularities $\Sigma$ (more precisely, the spaces $\mathcal{M}(\Sigma)$ of pairs $(B, c)$, where $B$ is a sextic and $c$ is an involutive stable symmetry of $B$) can be identified with the spaces of sections $L$ of $\Sigma_2$ that are in a certain prescribed special position with respect to $B_2$. The latter are described in Sections 2.5 and 2.6; they are all rational. It remains to notice that the forgetful map $\mathcal{M}(\Sigma) \to \mathcal{M}(\Sigma)$ is one to one, as any two stable involutions of a sextic $B$ are projectively equivalent, see Remark 5.1.3. □

5.2.3. **Theorem.** Let $B$ be a sextic as in Theorem 5.1.1. Then the fundamental group $\pi_1(\mathbb{P}^2 \setminus B)$ factors to the group given by (4.3.9).

5.2.4. **Remark.** The groups of most maximal sextics $B$ as in Theorem 5.1.1 are computed in Sections 4.1–4.7. Perturbing $L$, one can easily see that, if $B$ has exactly two components, the quartic component of $B$ has a set of singularities other than $3A_2$, and $\mu(B) < 19$, then $\pi_1(\mathbb{P}^2 \setminus B)$ is the group given by (4.3.9).

**Proof.** Any sextic as in Theorem 5.1.1 can be perturbed to a ‘simplest’ one, with the set of singularities $(2A_5 \oplus 2A_2) \oplus 2A_1$, which is the double of $B_2$ ramified at a section $L$ transversal to $B_2$. The group of a simplest sextic is (4.3.9), see, e.g., Section 4.3. □

5.3. **Proof of Theorem 1.1.2.** Let $P$ be the type $A_{17}$ singular point, and let $\Sigma_P \subset \Sigma \subset S \subset L$ etc. be as in the proof of Theorem 5.1.1. Denote $S_P = \Sigma_P \oplus (h)$. Since the sextic is reducible and of torus type, the intersection $K' = K \cap \text{discr} S_P$ contains an element of order 2 and an element of order 3, see [5] and [3]. On the other hand, $|\text{discr} S_P| = 36$; hence, $(K')_{2}\cap K' = 0$, i.e., the primitive hull of $S_P$ in $L$ is unimodular and the classification of homological types reduces to the study of sublattices isomorphic to $0$, $A_1$, $2A_1$, or $A_2$ in the direct sum of two hyperbolic planes. The rest is straightforward. □
5.3.1. Remark. From the proof, it follows that each sextic \( B \) as in Theorem 1.1.2 admits a stable involutive symmetry \( c \) (constructed as in the proof of Theorem 5.1.1 starting from the nontrivial symmetry of \( \Gamma_F \)). However, one has \( O_c \subset B \); hence, the quotient \( B/c \subset \Sigma_2 \) is not a trigonal curve but rather a hyperelliptic curve with a type \( A_7 \) singular point at \( E \). Thus, Conjecture 4.2.3 in [9] needs to be modified to include maximal, in some sense, hyperelliptic curves as well.

6. OTHER FUNDAMENTAL GROUPS

We consider a triple \( \tilde{B}'_2, \tilde{L}', \tilde{L} \) as in \( \S 4 \) and make \( \tilde{L} \) and \( \tilde{L}' \) trade rôles, i.e., we let \( \tilde{B} = B'_2 + \tilde{L} \) and consider the double \( B = \text{Dbl}_{\tilde{L}}(B'_2 + \tilde{L}) \) ramified at \( \tilde{L}' \). The groups \( \pi_1(\Sigma_2 \setminus (B'_2 \cup \tilde{L}' \cup \tilde{L} \cup E)) \) are computed in \( \S 4 \), and we merely use an appropriately modified version of Lemma 3.1.2 (with the rôle of \( \delta \) played by the generator corresponding to \( \tilde{L}' \)) to obtain \( \pi_1(\mathbb{P}^2 \setminus B) \). Then, as in \( \S 4 \), we perturb \( B \) to an irreducible sextic \( B' \) and apply Lemmas 3.5.1–3.5.6.

6.1. The set of singularities \( 2E_7 \oplus D_5 \). Take for \( \tilde{L} \) the section given by (2.5.4), see Section 4.4 and Figure 10 (the solid grey line). The resulting sextic \( B \) has the set of singularities \( 2E_7 \oplus D_5 \), and the group \( \pi_1(\mathbb{P}^2 \setminus B) \) is obtained from (4.1) by letting \( \beta^2 = 1 \) and passing to the subgroup generated by \( \alpha, \tilde{\alpha} = \beta \alpha \beta, \delta, \) and \( \tilde{\delta} = \beta \delta \beta \). One has \( \delta = \tilde{\delta} \) and hence

\[
(6.1.1) \quad \pi_1(\mathbb{P}^2 \setminus B) = \langle \alpha, \tilde{\alpha}, \delta | \alpha \tilde{\alpha} \alpha = \tilde{\alpha} \alpha \tilde{\alpha}, [\alpha, \delta] = [\tilde{\alpha}, \delta] = 1, \alpha^2 \delta^2 \beta^2 = 1 \rangle.
\]

The irreducible perturbation \( D_5 \hookrightarrow A_4 \) produces the set of singularities

\[
2E_7 \oplus A_4
\]

and adds the relation \( \alpha = \tilde{\alpha} = \delta \), see Lemma 3.5.4. The irreducible perturbations \( E_7 \hookrightarrow E_6, A_5, \) or \( A_4 \oplus A_2 \) of one of the two type \( E_7 \) singular points of \( B \) produce the sets of singularities

\[
E_7 \oplus E_6 \oplus D_5, \quad E_7 \oplus D_5 \oplus A_6, \quad E_7 \oplus D_5 \oplus A_4 \oplus A_2
\]

while adding at least the relation \( \alpha \tilde{\alpha} \alpha = \delta \alpha \delta \) (or \( \gamma \delta \gamma = \delta \gamma \delta \), where \( \gamma = \alpha^{-1} \tilde{\alpha} \alpha \)), see Lemma 3.5.6 and (3.5.7). In each case, it is immediate that the resulting fundamental group \( \pi_1(\mathbb{P}^2 \setminus B') \) is abelian.

6.2. The set of singularities \( 2E_7 \oplus A_3 \oplus A_2 \). Take for \( \tilde{L} \) the section given by (2.5.5), see the dotted grey line in Figure 10. A presentation for the group \( \pi_1(\Sigma_2 \setminus (B \cup \tilde{L}' \cup E)) \) is found in Section 4.5. To pass to \( \pi_1(\mathbb{P}^2 \setminus B) \), we let \( \beta^2 = 1 \) and consider the subgroup generated by \( \alpha, \tilde{\alpha} = \beta \alpha \beta, \gamma, \tilde{\gamma} = \beta \gamma \beta, \delta, \) and \( \tilde{\delta} = \beta \delta \beta \). The relations are

\[
(6.2.1) \quad \alpha \tilde{\alpha} \alpha = \tilde{\alpha} \alpha \tilde{\alpha},
\]

\[
(6.2.2) \quad \alpha \tilde{\alpha}^{-1} = \gamma, \quad \tilde{\alpha} \alpha \tilde{\alpha}^{-1} = \tilde{\gamma},
\]

\[
(6.2.3) \quad \alpha^{-1} \delta \alpha = \tilde{\alpha}^{-1} \tilde{\delta} \alpha,
\]

\[
(6.2.4) \quad \delta \tilde{\gamma} = \gamma \delta = \tilde{\gamma} \delta = \tilde{\delta} \gamma,
\]

\[
(6.2.5) \quad \gamma \delta \alpha \tilde{\delta} \alpha = 1.
\]
The irreducible perturbation $A_3 \hookrightarrow A_2$ produces the set of singularities

$$2E_7 \oplus 2A_2$$

and adds the relation $\gamma = \hat{\gamma} = \delta = \hat{\delta}$. Then, comparing (6.2.2) and (6.2.3), one concludes that $\alpha = \hat{\alpha}$ and hence $\alpha = \gamma$. Thus, the group is abelian.

Consider a maximal irreducible perturbation of one of the two type $E_7$ singular points of $B$, producing irreducible sextics with the sets of singularities

$$E_7 \oplus A_6 \oplus A_3 \oplus A_2, \quad E_7 \oplus A_6 \oplus A_3 \oplus A_2, \quad E_7 \oplus A_4 \oplus A_3 \oplus 2A_2,$$

see Lemma 3.5.6. A generic real fiber close to $R_{\infty}$ (the type $E_7$ singular point of $B$) is over $x \gg 0$, and the standard generators in this fiber are $\alpha$, $(\beta \gamma \delta)(\beta \gamma \delta)^{-1} = \delta$, $\beta \gamma \delta^{-1}$, and $\beta$. Hence, the group $\pi_1(U \setminus B)$ of a Milnor ball about the point perturbed is generated by $\alpha$, $\delta$, and $\gamma$, and the perturbation adds at least the relation $\gamma \alpha \gamma = \hat{\delta} \gamma \alpha$ (the third relation in (3.5.7)). Using (6.2.4), the additional relation simplifies to $\alpha \gamma \gamma = \delta \gamma$. Hence, $\delta = \alpha \gamma \gamma^{-1} = \alpha$ (substituting to (6.2.2) and using (6.2.1)), $\alpha \gamma \gamma \delta = \alpha$ (from (6.2.3)), $\delta = \alpha \alpha \alpha^{-1} = \gamma$ (from (6.2.2)), $\gamma = \gamma$ and $[\gamma, \alpha] = 1$ (from (6.2.4) again), and $\alpha = \gamma = \gamma = \alpha$ (from (6.2.2)). Thus, the group is abelian.

**6.3. The set of singularities $2E_7 \oplus A_2 \oplus 3A_1$.** Consider the section $\hat{L}$ tangent to $\hat{L}'$ and tangent to $B'_2$ at its cusp $R_{\infty}$. It is given by $y = 3/4$. Choose the generators $(\eta_1, \eta_2, \eta_3, \eta_4) = (\alpha, \delta, \beta, \gamma)$ in a real fiber $F$ over $x \gg 0$.

We are only interested in the perturbation $E_7 \hookrightarrow A_6$ of both type $E_7$ singular points of $B$, producing an irreducible sextic with the set of singularities

$$2A_6 \oplus A_2 \oplus 3A_1.$$ 

This perturbation can be realized symmetrically, by perturbing the type $E_7$ singular point of $B$ in $\Sigma_2$. According to Lemma 3.5.6, this gives the relations $\alpha \delta = \beta$, and the monodromy about $R_1$ adds the relation $[\beta, \gamma] = 1$. Hence, the resulting group $\pi_1(\mathbb{P}^2 \setminus B')$ is abelian.

**6.4. The set of singularities $2D_5 \oplus A_7 \oplus A_2$.** Let $\hat{L}$ be the section given by (2.5.6), see the solid grey line in Figure 11. As in Section 4.6, the relations for $\pi_1(\mathbb{P}^2 \setminus B)$ are (6.2.1)-(6.2.3), (6.2.5), and the relations

$$(6.4.1) \quad \gamma \delta = \hat{\gamma} \delta, \quad \delta \gamma \delta \gamma = (\gamma \delta)^2, \quad \delta \gamma \delta \gamma = (\hat{\gamma} \delta)^2$$

replacing (6.2.4).

The irreducible perturbations $A_7 \hookrightarrow A_6$ or $A_4 \oplus A_2$, see Lemma 3.5.3, produce the sets of singularities

$$2D_5 \oplus A_6 \oplus A_2, \quad 2D_5 \oplus A_4 \oplus 2A_2$$

and add the relations $\gamma = \hat{\gamma} = \delta = \hat{\delta}$. As in Section 4.6, the resulting groups are abelian. The irreducible perturbation $D_5 \hookrightarrow A_4$ of one of the type $D_5$ singular points produces the set of singularities

$$D_5 \oplus A_7 \oplus A_4 \oplus A_2.$$ 

The standard generators in a generic fiber close to $R_{\infty}$ (a fiber over $x \gg 0$) are $\alpha$, $(\beta \gamma \delta)(\beta \gamma \delta)^{-1}$, $(\beta \gamma \delta)(\beta \gamma \delta)^{-1}$, and $\beta$. In view of Lemma 3.5.4, the extra relations added to the group are $\alpha = (\gamma \delta \gamma \delta)^{-1} = \gamma \delta \gamma \delta^{-1}$. This implies $\alpha = \hat{\gamma} = \delta$, and using (6.2.1)-(6.2.3) one derives that $\alpha = \hat{\alpha} = \gamma = \hat{\delta}$. Hence, the group is abelian.
6.5. The set of singularities $3D_5 \oplus A_3$. Let $\tilde{L}$ be the section given by (2.5.7), see the dotted grey line in Figure 11. Starting from the presentation found in Section 4.7, letting $\beta^2 = 1$, and passing to the subgroup generated by $\alpha, \tilde{\alpha} = \beta \alpha \beta, \gamma, \tilde{\gamma} = \beta \gamma \beta, \delta, \tilde{\delta} = \beta \delta \beta$, we obtain the following relations for $\pi_1(\mathbb{P}^2 \setminus B)$:

\[
\begin{align*}
\delta \gamma &= \delta \tilde{\gamma} = \gamma \tilde{\gamma} = \gamma \delta, \\
\delta \alpha &= \alpha \delta, \quad \delta \tilde{\alpha} = \tilde{\alpha} \delta, \\
\delta \alpha \tilde{\alpha} &= \delta \tilde{\alpha} \alpha, \\
\alpha^{-1} \tilde{\alpha} \alpha &= \gamma, \quad \tilde{\alpha}^{-1} \alpha \tilde{\alpha} = \tilde{\gamma}, \\
\delta \gamma \alpha \delta \tilde{\gamma} \alpha &= 1.
\end{align*}
\]

The irreducible perturbation $A_3 \mapsto A_2$ produces the set of singularities

$$3D_5 \oplus A_2,$$

adding the relation $\gamma = \tilde{\gamma} = \delta = \tilde{\delta}$. The irreducible perturbation $D_5 \mapsto A_4$ of one of the type $D_5$ singular points of $B$ produces the set of singularities

$$2D_5 \oplus A_4 \oplus A_3,$$

adding the relation $\alpha = \tilde{\alpha} = \delta = \tilde{\delta}$, see Lemma 3.5.4. (We can assume that the point perturbed is over $B_5$.) It is straightforward that, in both cases, the new fundamental group is abelian.

6.6. Concluding remarks. The groups of all reducible curves obtained in this section are non-abelian; they all factor to the ‘minimal’ group $G$ given by (6.1.1), which can also be described as a central extension

$$1 \to \langle \delta \rangle \to G \to A_4 \to 1.$$

This result is quite expectable, as all curves split into a conic $B_2$ and a three cuspidal quartic $B_4$, and $\pi_1(\mathbb{P}^2 \setminus B_4) = A_4$.

It is worth mentioning that all curves admit regular $S_3$-coverings while obviously not being of torus type. Hence, Theorem 4.1.1 in [5] does not extend to reducible curves literally. Certainly, the reason is the fact that the cyclic part of the covering is not ramified at $B$ but rather at $B_4$ only.

In most cases, the trigonal curve $B = B_5 + \tilde{L} \subset \Sigma_2$ used in the construction is maximal, with the set of singularities $E_7 \oplus A_1$ or $D_5 \oplus A_3$. Thus, one may hope that the deck translation is a stable symmetry of the covering sextic $B$ (cf. Conjecture 4.2.3 in [9]) and use this correspondence to classify sextics.

In the former case, the set of singularities $E_7 \oplus A_1$, the sextics are characterized by the splitting $B = B_4 + B_2$, where $B_4$ is a quartic with at least two cusps and $B_2$ is a conic (possibly reducible) tangent to $B_4$ at two of its cusps. Any such curve is indeed symmetric: in appropriate affine coordinates $(x, y)$ in $\mathbb{P}^2$, the curves $B_1$ and $B_2$ can be given by $a + b(x + y) + cx^2 y^2 = 0$ and $d + exy = 0$, respectively. There are 13 deformation families of such curves, of which four are maximal. Three maximal families are considered in Sections 6.1–6.3; the fourth one has the set of singularities $2E_7 \oplus D_4 \oplus A_1$ (the conic $B_2$ splits and the quartic $B_4$ has an extra node and passes through the node of $B_2$).
In the latter case, the set of singularities $\mathbf{D}_5 \oplus \mathbf{A}_3$, the sextic splits into $B_4 + B_2'$, where $B_4$ is a quartic with at least two cusps and $B_2'$ is a conic passing through two cusps of $B_4$ and tangent to $B_4$ at all other intersection points. It appears that this configuration, as well as most of its degenerations, is realized by several equisingular deformation families, only one of them admitting a stable symmetry. The symmetric sextics seem to be related to the sextics of torus type considered in §5: they are obtained by replacing the conic $B_2$ in the splitting $B = B_4 + B_2$, see Theorem 5.1.1, by the conic $B_2' = \{ p = 0 \}$, where $p^3 + q^2 = 0$ is the (only) torus structure on $B$. (From the point of view of the trigonal curve, we replace the $\tilde{L}'$ component in $B_2 = B_2' + \tilde{L}'$ with the section passing through $R_\infty$ and tangent to $B_2'$ at $R_2$.) We will treat this subject in details elsewhere.

Note that each double $B = \text{Dbl}_L \tilde{B}$ of the trigonal curve $\tilde{B}$ with the set of singularities $\mathbf{D}_5 \oplus \mathbf{A}_3$ has non-abelian fundamental group: all groups factor to the ‘simplest’ one, corresponding to the case when $L$ is transversal to $\tilde{B}$. Letting $\alpha = \alpha$, $\gamma = \gamma$, and $\delta = \delta$ in the presentation in Section 6.4, we obtain the following presentation for the simplest group $G$:

$$G = \langle \gamma, \delta | (\gamma \delta)^2 = (\delta \gamma)^2, (\gamma \delta \gamma)^2 = 1 \rangle.$$ 

Introducing new generators $u = \delta \gamma$, $v = \gamma \delta \gamma$, we can simplify the presentation to $G = \langle u, v | u^2 = [v, u^2] = 1 \rangle$. It is clear that the commutant $[G, G]$ equals $\mathbb{Z}$, both $u$ and $v$ acting on $[G, G]$ by the multiplication by $(-1)$. In particular, all curves admit regular $\mathbb{D}_{2n}$-coverings for any $n \geq 3$; however, they are not $\mathbb{D}_{2n}$-sextics.

7. Summary

We summarize the results on the fundamental group of an irreducible plane sextic obtained in this paper and combine them with [8] and [10]. We confine ourselves to the case of simple singularities only; the groups of sextics with a non-simple singular point are essentially found in [5] and [6] (see also Oka, Pho [21]).

7.1. Sextic of torus type. According to Oka, Pho [20], there are 19 tame and 109 non-tame sets of simple singularities realized by irreducible plane sextics of torus type. At present, the fundamental group is known for 113 sets of singularities, including all tame ones. The result is summarized in Table 1, where ‘nt#’ is the notation introduced in [20] and the last column indicates a proof, either by referring to the appropriate paper/section or by suggesting a degeneration (in the form ‘$\rightarrow$ nt#’). We only list the sets of singularities for which the degenerations suggested in [20] lead to sextics whose groups are still unknown.

With few exceptions, the fundamental group of an irreducible sextic of torus type is Zariski’s group $\mathbb{Z}_3 \cong \mathbb{Z}_2 \ast \mathbb{Z}_3$. The known exceptions are

- sextics of weight 8 and 9 in the sense of [5], see [8];
- sextics marked with a * in Table 1, see references in the table;
- the set of singularities $2E_6 \oplus 2A_2 \oplus 2A_1$, see [10].

Various perturbations of the exceptional sextics are studied explicitly in [8] and [10]; all other groups are given by Corollary 3.6.2.

7.1.1. Remark. For most non-maximal sets of singularities, the connectedness of the equisingular deformation family is still unknown, although expected, see

Conjecture 1.2.1. For these sets of singularities, we can only state the result in the form of existence, i.e., to assert that there is a sextic B of torus type realizing a given set of singularities and such that \( \pi_1(\mathbb{P}^2 \setminus B) = \mathbb{Z}_3 \). To my knowledge, the sets of singularities for which the classification is completed are:

- sextics admitting a stable involutive symmetry, see [9] for the list and [8], [10], and Theorem 1.1.1 for the classification;
- the sets of singularities of the form (inner points) ⊕ kA₁, see [3] and [22].

The fifteen remaining sets of singularities, for which the fundamental group is still unknown, are listed in Table 2 (with a reference to the notation of [20]).

### 7.2. Sextics with abelian fundamental groups.

In Table 3, we list the sets of singularities realized by irreducible plane sextics with abelian fundamental group, together with the references to the sections where these curves are constructed. Combining these results with [8] and [10] and considering all perturbations, we obtain 768 sets of singularities not covered by Nori’s theorem [17].

### 7.3. Classical Zariski pairs.

The list resulting from Table 1 contains a number of sextics of weight 7 with at least two cusps. Perturbing a cusp of such a sextic, we

obtain 30 so called classical Zariski pairs, i.e., pairs of irreducible sextics that share the same set of singularities but differ by their Alexander polynomials (see [3] for details and further references; the sextic is/is not of torus type if the cusp perturbed is, respectively, outer/inner). One can add to this list the sets of singularities

\[(7.3.1) \quad E_6 \oplus A_{11}, \quad E_6 \oplus A_8 \oplus A_2, \quad A_{17}, \quad A_{11} \oplus A_5, \quad 2A_8,\]

which are realized by sextics with abelian fundamental groups in Eyral, Oka [12], thus obtaining 35 classical Zariski pairs. (Sextics of torus type realizing (7.3.1) are constructed in this paper. The two other sets of singularities discovered in [12] are already on the list.) In each pair, the groups of the two curves are $\mathbb{Z}_3$ and $\mathbb{Z}_6$.

According to [3] and [22], each of the 35 sets of singularities obtained above is realized by exactly two equisingular deformation families of irreducible sextics, one of torus type and one not. Altogether, there are 51 classical Zariski pairs of
irreducible sextics (one of them being, in fact, a triple). For all but one of them (the set of singularities $\left(A_{14} \oplus A_2, \oplus 2A_1\right)$, the group of the curve of torus type is known; it equals $\mathbb{B}_3$.
