ABSTRACT

With the rapid growth of digital photography, sharing of photos with friends and family has become very popular. When people share their photos, they usually organize them in albums according to events or places. To tell the story of some important events in one’s life, it is desirable to have an efficient summarization tool which can help people to get a quick overview of an album containing huge number of photos. In this paper, we analyze our approach for photo album summarization through a novel social game “Epitome” as a Facebook application. Our social game can collect research data and, at the same time, it provides a collage or a cover photo of the user’s photo album, while, at the same time, the user enjoys playing the game. As a benchmark comparison to this game, we performed automatic visual analysis considering several state-of-the-art features.

1. INTRODUCTION

Rapid growth of digital photography in recent years has increased the size of personal photo collections. People use their digital cameras or mobile phones equipped with cameras to take photos. Beside storing them on computer hard drives, people also share their digital photos with friends, family and colleagues through social networks. Facebook1, Flickr2 and Picasa3 are examples of such photo sharing web sites. Some people also print their photos on post cards, calendars or photo books, often to give them as presents or to create physical souvenirs.

Users usually organize their photos in albums (collections) based on places, events or people. By sharing these albums with others, they want to tell their own stories of some important events in their life, such as birthday party, vacation, wedding, or birth of a baby. It can be very time-consuming to go through all photos in one album, and therefore summarization is an effective way to help getting a quick overview of a set of photos. Album summarization can be defined as selecting a set of photos from a larger collection which best represents the visual information of the entire collection. Selected photos can be used to create a collage of a given album, a cover for an album, or to be included in a photo book.

Current state-of-the-art techniques are based on automatic summarization which considers time separated events, spatial information using GPS coordinates and content-based image similarities. Naaman et al. [5] developed a system which does automatic organization of digital photographs considering the geographic location of photo or event based description extracted from user tags. Combination of spatial, temporal and content-based similarity is then used for photo collection clustering. This clustering can be used for photo navigation and search for different categories, such as elevation, season, time of the day, location, weather status, temperature and time zone. Once photos are clustered, different page layouts should be considered. Geigel and Loui [3] emphasized aesthetic side of a page layout for image collections. They used a genetic algorithm to optimize aspects such as balance and symmetry for a good placement of images in the personalized album pages. An automatic summarization has its limitations. There is a gap between what people think the summary should look like and what we get with an automatic summarization.

Ames and Naaman [2] showed that providing incentives to the user in form of entertainment or rewards, e.g. games, can motivate them to tag photos in online and mobile environments. Gaming also provides a new way of motivating people to make the subjective data acquisition interesting and enjoyable. The most famous examples of these kind of games are the ESP Game and Peekaboom, developed for

choose the best representative photo. If the player chooses the photo which is the most frequently selected by other players, then player’s score increases. The second game is called “Split it!” where the player should split images into two parts which have distinct semantic meanings. In this game, the photos are shown in the time order in which they were captured. The time stamp is extracted from EXIF tags associated to each photo. The results of “Select the Best!” and “Split it!” games are combined to form a score and if a user reaches a certain score level, then the photos for the collage of the user’s photo album are shown to the owner. Therefore, the player can get a feedback from all other players, regarding his/her Facebook photo albums. The game has appealing look using different visual and audio effects, as shown in Figure 1.

The application calculates three different values: Importance, Segmentation and UserScore. Importance value is determined in the “Select the Best!” game for each photo album separately. The goal of this game is to select the most representative photo of the particular Facebook album of K = 9 photos given the fact that the players can select only one representative photo among K randomly chosen photos. A feature vector $BestSmall_n$, $n \in [1, N]$, is calculated for each player, n among N players, as follows:

$$BestSmall_n = [\alpha_{n,1}, \alpha_{n,2}, \alpha_{n,3}, \ldots, \alpha_{n,K}], (1)$$

where $\alpha_k \in \{0, 1\}$, for $k \in [1, K]$, is either 1 or 0 depending on whether the corresponding photo is chosen as the most representative photo. This vector is then expanded to a vector $Best_n$ of dimension $M$, where $M$ is the size of a particular Facebook album, as follows:

$$Best_n = \left[ \begin{array}{c} 0, \ldots, 0, \frac{BestSmall_n}{K}, 0, \ldots, 0 \end{array} \right], \quad M - K - y + 1 \leq y \leq 1 \quad (2)$$

where $y \in [1, M - K + 1]$ is the index of the first photo shown to the player. A vector $BestFreq$ of dimension $M$ stores the frequency of all photos that appear in the game. An $M$-dimensional vector $BestCount$ is then calculated as:

$$BestCount = \sum_n Best_n, \quad n \in [1, N].$$

At the end, we perform normalization on vector $BestCount$ by element-wise division:

$$Importance = \frac{BestCount}{BestFreq}. (3)$$

which is an $M$-dimensional vector showing the distribution of the most representative photos within one Facebook album.

Segmentation vector is calculated in “Split it!” game for each photo album separately in an analogous way as explained for Importance value. It shows the frequency with which each photo in one album is selected as starting photo in a new segment.

Finally, vectors Importance and Segmentation are used to automatically select $L = 5$ most representative photos within one Facebook photo album. At first, the particular album is segmented into $L$ most probable segments by determining $L - 1$ maximum values from the vector Segmentation. For each of these segments, a photo with the highest score in the vector Importance is chosen. These L photos represent a collage of the album, which is shown to the owner of that album, if he/she reaches a certain level of UserScore.

2. EPITOME GAME

The goal of our application is to provide an intuitive and enjoyable user interface as a Facebook application, which creates and annotates photo collages for Facebook photo albums. Therefore, the game “Epitome” is created, which can provide its potential users with many pleasant hours while playing it, and enjoying photos. At the same time, it de-

The paper is organized as follows. Our social game application and its implementation is presented in Section 2. Experiments and results are discussed in Section 3. Finally, Section 4 concludes the paper with a summary and some perspectives for future study.

Figure 1: Main game selection, “Select the Best!” screenshots of the games are shown.
The dataset used in our experiments is the official dataset from “HP Challenge 2010: High Impact Visual Communication” at the “Multimedia Grand Challenge 2010” [1]. It consists of 6 datasets, each with 20 photos. These datasets cover photos that are usually taken during a vacation, describing a variety of topics: photos depicting different landmarks and famous sightseeing places, photos with parents and kids, and photos of cars, flowers and sea animals. Figure 4 provides example photos of the datasets.

3.2 Experiments
To collect the ground truth data and to evaluate the designed photo selection tool (social game), we conducted two experiments. Since there are different criteria upon which a human user would rate digital photos, we first constructed a ground truth by asking different people for their subjective opinion about photos and then tested our algorithm against the ground truth data. We recruited 63 participants, among whom 61% were males and 39% were females, aged 18 – 65, with different backgrounds and cultural differences.

In the collection of the ground truth data, participants were shown 20 photos which belong to the same dataset (collection or album). The task of the participants was to select the 5 most representative photos of the whole album, while looking at all photos of that album.

Then, participants were asked to play two games “Select the Best!” and “Split it!” with a dataset from Section 3.1. The results obtained from these games are used to assess the performance of our approach by comparing them with the ground truth and results from automatic visual analysis.

Furthermore, we performed automatic photo album summarization considering different visual and temporal features. At first "Bag of Words" method based on SURF features, "Histogram of Oriented Gradients", "HSV Color histogram" and "Tiny" features are extracted. Where "Tiny" feature is used as benchmark representing scaled 32x32 grayscale tiny images. The dimensions of the features are around 1000. Moreover creation time stamp is extracted from EXIF for further analysis. We segment the album into 5 parts by extracting the four highest Euclidean distances of the consecutive photos’ features. For each image in the particular segment, we calculate the sum of the Euclidean distances between that feature of the photo and the rest of the image features in the segment. The image with the lowest sum is then selected as the most representative photo in that segment. Different features can be used for segmentation and to select the most representative photo in the segments. Therefore we calculated the performance of 20 different feature pairs.

3.3 Results and analysis
For simplicity of the explanation on how our approach was evaluated, let us consider only one dataset with $M = 20$ photos. First, a ground truth data is collected. Every user $n$ among $N = 63$ users is asked to select the 5 most representative photos. After his/her participation in collecting the ground truth data, the corresponding feature vector $Full_n$, $n \in [1, N]$, is formed as follows:

$$F ull_n = [\delta_{n,1}, \delta_{n,2}, \delta_{n,3}, \ldots, \delta_{n,M}], \quad (4)$$

where $\delta_{n,m} \in \{0, 1\}$, for $m \in [1, M]$, takes either 1 or 0 depending on whether the corresponding photo is chosen as one of the representative photos or not. Feature vectors of the users $i$ and $j$, $i, j \in [1, N]$, are then compared to each other and the score of their matching $S_{i,j}$ is calculated as:

$$S_{i,j} = F ull_i \cdot F ull_j^T.$$

In other words, the higher the number of identical photos that are chosen by two users, the better will be the score of the match between them. Note that the maximum score of the match is 5. Finally, to each user $i$, $i \in [1, N]$, a value $Score_i$ is assigned as: $Score_i = \sum_{j=1}^{N} S_{i,j}$. The maximum value in the vector $Score_i$ shows the best performing participant who has the highest number of selected photos which are matched with all other users. The maximum possible value of the score is 5XN, which in our case becomes 315. These results are considered as the ground truth data and compared with the results obtained from the games in order to prove the concept of our approach. All computations are repeated in a similar way for all 6 datasets.

Furthermore, the results obtained in this game are compared with the results of an automatic image selection by making use of visual and time features. We calculated the performance of 20 different feature pairs as shown in Figure 2. The result shows that the best performance is achieved by ”Color histogram” for both, album segmentation and best photo selection in the segment. Which shows the robustness of the ”Color histogram” features to any kind of images.

Figure 3 shows the distribution of the participants’ scores, including the choice of the proposed method and the automatic visual analysis. All scores are sorted in a descending order.

order. These results look promising. As we can see, the scores of the proposed method have a small relative distance from the best ground truth scores achieved in our experiments. In average, our approach achieves 80% of the best score for each dataset, which proves the concept of our game. It also outperforms the automatic visual analysis. For datasets 3 and 5, this value is even higher, i.e. about 95%. The most representative photos for one of the datasets selected by the proposed method are shown in Figure 4.

Finally, we discuss user feedback related to our game and automatic summarization as shown in Table 1. The main disadvantage of our game is that the user has to wait maybe several days for the generated album collage, however we showed that it outperforms the automatic analysis. The main advantage of the game is that the user enjoys it and they receive interesting feedback from his friends about his photo albums.

4. CONCLUSION

In this paper, we analyzed a social games for an album summarization on Facebook. The proof of concept of these games was demonstrated and validated through a set of experiments on several photo collections. The results of our experiments show that our summarization game achieves 80% of the best score of different participants and significantly outperforms automatic visual summarization methods. As a future study, we will include in our approach more sophisticated visual analysis and make the game more attractive for users.
