ABSTRACT: A novel series of ionic liquids composed of imidazolium, pyridinium, pyrrolidinium, and ammonium cations with tricyanomethanide or tetracyanoborate anions were prepared. The ionic liquids were characterized by NMR and IR spectroscopy and ESI-mass spectrometry, and their physical properties were investigated. Solid state structures of the N-propyl-N-methylpyrrolidinium and triethylpropylammonium tetracyanoborate salts were obtained by single crystal X-ray diffraction. The salts that are liquid at room temperature were evaluated as electrolyte additives in dye-sensitized solar cells, giving rise to efficiencies 7.35 and 7.85% under 100 and 10% Sun, respectively, in combination with the standard Z907 dye.

INTRODUCTION

Despite the ongoing interest in ionic liquids (ILs), the majority of the research is based on ILs containing a rather limited set of fluorine-containing anions, notably tetrafluoroborate ($\text{BF}_4^-$), hexafluorophosphate ($\text{PF}_6^-$), and bis(trifluoromethylsulfonyl)imide ($\text{Tf}_2\text{N}^-$). In contrast, ILs based on nonfluorous anions, i.e., tricyanomethanide ($[\text{C(CN)}_3]^{-}$) and tetracyanoborate ($[\text{B(CN)}_4]^{-}$), are relatively low given the cation.

Some of the room temperature ILs were employed as electrolytes in dye-sensitized solar cells giving very good efficiencies exceeding 7%.

RESULTS AND DISCUSSION

The preparation of ILs with $\text{BF}_4^-$, $\text{PF}_6^-$, and $\text{Tf}_2\text{N}^-$ anions is well established, whereas there are relatively few reports describing the synthesis of ILs with $[\text{C(CN)}_3]^{-}$ anions. The synthesis of ILs with $[\text{B(CN)}_4]^{-}$ anions is only covered in a patent, and details of the anion exchange of the alkali metal salts of tetracyanoborate with imidazolium or pyridinium halides have not been reported. In this work, we used a literature protocol to react 1-propyl-3-methylimidazolium chloride ($[\text{PMI}]\text{Cl}$) with Na$[\text{C(CN)}_3]$ in aqueous solution, and the resulting IL, $[\text{PMI}][\text{C(CN)}_3]$ (1a), was extracted with dichloromethane. Similarly, reaction of $[\text{PMI}]\text{Cl}$ with K$[\text{B(CN)}_4]$ gives the IL $[\text{PMI}][\text{B(CN)}_4]$ (1b). Using the same approach, ILs containing N-propylpyridinium, N-propyl-N-methylpyrrolidinium, and triethylpropylammonium cations with the $[\text{C(CN)}_3]^{-}$ anion (2a–4a) and the $[\text{B(CN)}_4]^{-}$ anion (2b–4b) were prepared (see Figure 1).

In this paper, the synthesis and characterization of a series of new ILs with $[\text{C(CN)}_3]^{-}$ and $[\text{B(CN)}_4]^{-}$ anions are described.
anion, i.e., 1b–4b, only 1b and 2b are liquid at room temperature. The 1H and 13C NMR spectra of 1a–4a, 1b, and 2b are recorded as ILs without being dissolved in any solvent using a C6D6 capillary for login. Spectra of 3b and 4b were obtained in a CD2Cl2 solution (see the Experimental Section). The IR spectra of 1b–4a contain absorptions between 2153 and 2164 cm−1 that correspond to the C=–N bond; the absorptions lie in a rather smaller range compared to those observed in salts with metal cations.21–24 In 1b–4b, the absorptions of the CN group are observed at markedly higher wavenumbers (ca. 2222 cm−1) and are significantly shifted from those containing metal cations, which are found in the range of 2250 to 2290 cm−1,25–27 but nonetheless are close in value to those observed in tetrabutylammonium28 and tetrabutylphosphonium29 salts. It is known that the C=–N absorption in salts containing [C(CN)3]− and [B(CN)4]− anions is sensitive to the structure of the cations and is susceptible to π···π and/or π···H noncovalent interactions.24

Although salts containing the tetracyanoborate anion were reported many years ago,30 the structure of simple lithium salt was reported only recently,31 followed by the structures of potassium,32 sodium, rubidium, cesium, and ammonium salts;25 several transition metal salts36,26,27 and somewhat more exotic salts.33 Single crystals of 3b and 4b were obtained by slow cooling from the liquid state from 110 °C over a period of 24 h, and their structures were determined by X-ray diffraction (see the Experimental Section). Only very few salts with organic cations (e.g., tetrabutylphosphonium and tetrabutylammonium salts) have been reported,28,29 and the structures of 3b and 4b (Figure 2) represent the first examples of tetracyanoborate salts containing asymmetric cations.

In 3b and 4b, the anion adopts a nearly ideal tetrahedral structure with the C–B–C angles close to 109.4° and B–C–N angles close to 180°. The average C–N distance in the nitrile groups is 1.14 Å in 3b and 4b, nearly the same as those observed in the lithium (1.14 Å)31 and potassium (1.14 Å) salts.32 These values are in the range found in the ammonium and phosphonium salts.28,29 In the crystal of 3b, the anions are connected by weak hydrogen bonds forming a C=–H···N=C–B=C–N···H···C network (Figure 3). The D–A distances of the C=–H···N hydrogen bonds range from 3.40 to 3.53 Å (Figure 3 and Table 1). These distances are rather longer than those that exist in series of imidazolium salts with other anions such as Tf2N− and BF4−.34,35 The CH3 group of the propyl substituent in 4b is disordered, but hydrogen bonds are observed between the CH3 group of the ethyl substituents and the anion, with the shortest (C)–H···N distance being 2.63 Å.

The room temperature ILs 1a/b, 2a/b, 3a, and 4a were used to prepare electrolytes, and their viscosities and tri-iodide diffusion coefficients were determined. Subsequently, they were evaluated in dye-sensitized solar cells following the procedure described for the standard eutectic melt electrolyte coded Z952.14 Essentially, the new ILs were incorporated into the electrolytes in place of 1-ethyl-3-methylimidazolium tricyanomethane [EMI][C(CN)3] at the same molar ratio, giving electrolytes termed M-1a, M-1b, M-2a, M-2b, M-3a, and M-4a (see the Experimental Section).

The electrolytes with [C(CN)3]− are less viscous than their [B(CN)4]− analogues (namely M-1a vs M-1b and M-2a vs M-2b). Diffusion coefficients of I3− were obtained by cyclic voltammetry and electrochemical impedance spectroscopy (EIS) performed on symmetric cells, and the results obtained by these two methods are shown in Table 2. Electrolytes M-1a and M-2a have slightly higher tri-iodide diffusion coefficients, presumably due to their lower viscosity.
The six new electrolytes have been formulated for use in DSC devices in combination with Z907 as a sensitizer (Table 3). The best DSC device contains the electrolyte M-1a; the open-circuit voltage (V<sub>oc</sub>), short-circuit current density (J<sub>sc</sub>), and fill factor (FF) are 725 mV, 13.7 mA/cm<sup>2</sup>, and 0.743, respectively, yielding an overall photoconversion efficiency (PCE) of 7.35% at full sunlight intensity. However, the PCE at 10% light intensity is as high as 7.85% due to diminished problems with diffusion connected with slower cell dynamics under these light conditions. The J–V curves of the device with electrolyte M-1a are presented in Figure 4. The incident photon-to-current efficiency (IPCE) of the device M-1a is shown in the inset of Figure 4. The maximum IPCE value at 550 nm is more than 70%. The DSC devices exhibit rather linear performance with an increasing intensity of irradiating light, and only a small current drop (∼5%) was noticed at 1 Sun, presumably due to mass transport limitations of tri-iodide.

There is a clear trend between the open circuit potential of the DSCs and the counter ion of the IL used in the electrolyte. Electrolytes containing the [C(CN)<sub>3</sub>]<sup>−</sup> anion exhibit higher V<sub>oc</sub> values, by ∼20 mV, compared to those with the [B(CN)<sub>4</sub>]<sup>−</sup> anion. We employed transient photovoltage decay measurements on the cells with different electrolytes to compare the rate of interfacial recombination of electrons from the TiO<sub>2</sub> conduction band to the oxidized form of the redox mediator, tri-iodide. In Figure 5, the apparent electron lifetime calculated for cells with the different electrolytes is plotted against extracted charge, which provides a clearer comparison, because the difference between the quasi-Fermi level and the conduction band is kept constant for each measured point.
It appears that the two anions, \([\text{C(CN)}_3]^-\) and \([\text{B(CN)}_4]^-\), do not influence the recombination rate, since the electron lifetimes for the electrolytes sharing the same cation are practically identical. Nevertheless, the planar \([\text{C(CN)}_3]^-\) anion\(^{35}\) could potentially facilitate access to the TiO\(_2\) surface, as it could adsorb on it more easily than the tetrahedral \([\text{B(CN)}_4]^-\) anion.\(^{35}\) Indeed, a more detailed comparison between the \([\text{B(CN)}_4]^-\) and dicynoamide, \([\text{N(CN)}_2]^-\), anions has been reported.\(^{37}\) It was found that \([\text{N(CN)}_2]^-\) containing electrolytes have higher open circuit potential than \([\text{B(CN)}_4]^-\) based electrolytes, and this difference was ascribed to suppressed interfacial charge-transfer behavior in addition to differences in the recombination rates, the specific adsorption of \([\text{C(CN)}_3]^-\) may be responsible for the upward shift of the conduction band of TiO\(_2\) especially as this difference corresponds very well with the difference between \(V_{oc}\) values of the devices (Figure 6) at a given density of states.

In conclusion, we have prepared and characterized a series of new fluorouros-free ILs containing imidazolium, pyridinium, pyrrolidinium, pyridinium, or ammonium halide was mixed with Na\([\text{C(CN)}_3]_2\) or K\([\text{B(CN)}_4]_2\) in a molar ratio of 1:1 in water (5 mL). After stirring at room temperature for 24 h, the reaction mixture was extracted with dichloromethane (3 × 10 mL). Removal of the dichloromethane gave the desired IL that was dissolved in dry dichloromethane and then stored at −20 °C for 24 h. The solution was filtered to remove traces of sodium or potassium halide, and after removal of the solvent, the product was dried under vacuum conditions.

**EXPERIMENTAL SECTION**

Imidazolium, pyridinium, pyrrolidinium, and ammonium halides were purchased from Iolitech (Germany) and used as received. Sodium tricyanomethanide Na\([\text{C(CN)}_3]_2\) and potassium tetracyanoborate K\([\text{B(CN)}_4]_2\) were received as a gift from Lonza AG and from Merck KGaA, respectively. IR spectra were recorded on a Perkin-Elmer FT-IR 2000 system. NMR spectra were measured on a Bruker DMX 400, using Me\(_4\)Si as an external standard. Electrospray ionization mass spectra (ESI-MS) were recorded on a ThermoFinnigan LCQ Deca XP Plus quadrupole ion trap instrument using a literature method.\(^{38}\) Elemental analysis was carried out at the EPFL.

1a: This IL was prepared from 1-propyl-3-methylimidazolium chloride (1.61 g, 0.01 mol) and Na\([\text{C(CN)}_3]_2\) (1.13 g, 0.01 mol). Yield: 95%. \(^1\)H NMR (Neat, C\(_6\)D\(_6\) capillary): 9.00 (s, 1H), 7.80 (s, 1H), 7.75 (s, 1H), 4.50 (t, 2H, \(J(\text{HH}) = 6.50\) Hz), 4.20 (s, 3H), 2.20 (m, 2H), 1.25 (t, 3H, \(J(\text{HH}) = 6.50\) Hz). \(^{13}\)C NMR (Neat, C\(_6\)D\(_6\) capillary): 136.5, 123.5, 122.5, 121.4, 36.0, 24.5, 11.0, 6.1. IR (cm\(^{-1}\)): 3114, 2970, 2164, 1573, 1456, 1169, 1066, 892. ESI-MS (CH\(_3\)CN) (m/z), positive ion: 125 [cation]. Negative ion: 90 [C\(_{11}\)N\(_6\)]\. Anal. Calcd for C\(_{11}\)H\(_{13}\)N\(_6\) (240.07): C, 55.03; H, 5.46; N, 35.01%. Found: C, 51.29; H, 6.07; N, 32.56%.

1b: This IL was prepared from 1-propyl-3-methylimidazolium chloride (1.00 g, 0.006 mol) and K\([\text{B(CN)}_4]_2\) (0.96 g, 0.006 mol). Yield: 97%. \(^1\)H NMR (Neat, C\(_6\)D\(_6\) capillary): 9.00 (s, 1H), 7.96 (s, 1H), 7.92 (s, 1H), 4.70 (t, 2H, \(J(\text{HH}) = 6.50\) Hz), 4.45 (s, 3H), 2.45 (m, 2H), 1.50 (t, 3H, \(J(\text{HH}) = 6.50\) Hz). \(^{13}\)C NMR (neat, C\(_6\)D\(_6\) capillary): 137.0, 123.5, 123.0, 122.2, 51.6, 37.1, 24.5, 11.0. IR (cm\(^{-1}\)): 3154, 3118, 2971, 2882, 2223, 1572, 1458, 1168, 931. ESI-MS (CH\(_3\)CN) (m/z), positive ion: 125 [cation]. Negative ion: 115 [K\([\text{B(CN)}_4]_2\)]\. Anal. Calcd for C\(_3\)H\(_9\)N\(_4\) (240.07): C, 55.03; H, 5.46; N, 35.01%. Found: C, 55.09; H, 5.66; N, 34.98%.

2a: This IL was prepared from N-propyl-pyridinium iodide (2.49 g, 0.01 mol) and Na\([\text{C(CN)}_3]_2\) (1.13 g, 0.01 mol) using the same procedure as described above. Yield: 98%. \(^1\)H NMR (Neat, C\(_6\)D\(_6\) capillary): 9.25 (d, 2H), 8.90 (d, 2H), 8.42 (d, 2H), 4.95 (t, 2H), 2.35 (m, 2H), 1.25 (t, 3H). \(^{13}\)C NMR (neat, C\(_6\)D\(_6\) capillary): 146.5, 145.5, 130.0, 121.6, 64.0, 31.0, 25.5, 11.0, 6.0. IR (cm\(^{-1}\)): 3064, 2971, 2153, 1636, 1488, 1227, 1171, 1066. ESI-MS (CH\(_3\)CN) (m/z), positive ion: 122 [cation]. Negative ion: 90 [anion]. Anal. Calcd for C\(_5\)H\(_9\)N\(_4\) (212.25): C, 67.91; H, 5.70; N, 26.40%. Found: C, 67.88; H, 5.68; N, 26.38%.

2b: This IL was prepared from N-propyl-pyridinium iodide (1.25 g, 0.005 mol) and K\([\text{B(CN)}_4]_2\) (0.77 g, 0.005 mol) using the same procedure as described above. Yield: 97%. \(^1\)H NMR (neat, C\(_6\)D\(_6\) capillary): 9.25 (d, 2H), 9.00 (d, 1H), 8.52 (d, 2H), 5.05 (t, 2H), 2.65 (m, 2H), 1.50 (t, 3H). \(^{13}\)C NMR (neat, C\(_6\)D\(_6\) capillary): 146.5, 145.5, 130.1, 122.4, 64.5, 25.5, 11.5. IR (cm\(^{-1}\)): 3070, 2972, 2222, 1637.
3a: This IL was prepared from N-propyl-N-methylpyrrolidinium chloride (1.30 g, 0.008 mol) and K[B(CN)4] (0.13 g, 0.001 mol) using the same procedure as described above. Yield: 95%. H NMR (neat, CD3D2 carapillar): 3.47 (m, 4H), 3.21 (t, 2H), 3.00 (s, 3H), 2.27 (m, 4H), 1.82 (m, 2H), 1.06 (t, 3H). 13C NMR (neat, CD3D2 carapillar): 121.8, 66.2, 55.3, 21.7, 17.3, 10.5. IR (cm−1): 2972, 2158, 1470, 1229, 1065, 938, 892. ESI-MS (CH3CN) (m/z), positive ion: 128 [cation]+. Negative ion: 90 [anion]−. Anal. Calcld for C21H28N5 (342.39): C, 66.02; H, 8.31; N, 25.67%. Found: C, 66.28; H, 8.40; N, 25.62%.

3b: This IL was prepared from triethylpyrrolidinium chloride (1.30 g, 0.008 mol) and K[B(CN)4] (1.23 g, 0.008 mol) using the same procedure as described above. Yield: 95%. Mp. = 78 °C. 1H NMR (CDCl3): 3.65 (m, 4H), 3.30 (t, 2H), 3.05 (s, 3H), 2.30 (m, 4H), 1.90 (m, 2H), 1.10 (t, 3H). 13C NMR (CDCl3): 122.8, 67.0, 66.5, 49.5, 22.5, 18.0, 10.5. IR (cm−1): 2983, 2887, 2223, 1462, 1407, 1001, 970, 926. ESI-MS (CH3CN) (m/z), positive ion: 128 [cation]+. Negative ion: 90 [anion]−. Anal. Calcld for C21H28N5 (342.39): C, 66.28; H, 8.40; N, 25.62%.

Crystals suitable for X-ray diffraction studies of 3b and 4b were obtained by slow cooling of the neat IL, 3b and 4b, from 110 °C to room temperature over 24 h. Data collection was performed on a KUMA CCD using graphite-monochromated Mo Kr (0.7073 Å) radiation and a low temperature device [T = 140(2) K]. Data reduction was performed using CrysAlis RED.39 The structure was solved with SHELXS97.40 Refinement was performed using the SHELX97 software package, and graphical representations of the structures were made with Diamond.35 All structure was solved by direct methods and successive interpretation of the difference Fourier maps, followed by full matrix least-squares refinement (against F2).41 All non-hydrogen atoms were refined anisotropically. The contribution of the hydrogen atoms, in their calculated positions, was included in the refinement using a riding model. Relevant details for the structure refinements of 3b and 4b are listed in Table 4.

Electrolyte Preparation. A state of the art eutectic ionic-liquid-based electrolyte15 was used as a model for further modifications. It comprises 1,3-dimethylimidazolium iodide ([EMI][I])/1-ethyl-3-methylimidazolium iodide ([EMI][I])/1-ethyl-3-methylimidazolium tetraacyanoborate ([EMI][B(CN)4])/iodine/N-n-butylbenzimidazole/guanidinium thiocyanate (6:6:8:0.3:1.67:0.33). For the purpose of this study, [EMI][B(CN)4] in the above-mentioned electrolyte was replaced at the same molar ratio by each of the synthesized ILs: 1a/b, 2a/b, 3a, and 4a, thus forming six new electrolytes coded as M-(respectile IL code).

Viscosity. Viscosity measurements of new modified electrolytes were determined using a HAAGE RheoStress I Rheometer (Thermo Scientific) with a HAAGE DC50 Thermostat (Thermo Scientific).

| Table 4. Crystal Data and Structure Refinement Details for 3b and 4b |

Experiments and data acquisition were supported by the HAAKE RheoWin software. A Ti cone of a diameter of 20 mm and an angle of 0.5° was used for all experiments. Samples were measured at 20 °C. The applied shear rate was in the range 10–8000 s⁻¹ for electrolytes (10–2000 s⁻¹ for pure ILs), and an equilibration time of 30 s was used for each point. In order to obtain a valid flow, a straight line was fitted to a plateau in the low shear rate region for each plot. A point for lowest applied shear rate (10 s⁻¹) was neglected due to the applied measurement procedure.

Device Fabrication. Photoanodes used to make the devices consisted of a screen-printed nanoparticulate mesoporous TiO2 layers. A 8-μm-thick transparent layer of 20-nm-sized TiO2 particles was first printed on the fluorine doped SnO2 (FTO) conducting glass (NSG-102/μm, 4-mm-thick) and subsequently coated with a 5-μm-thick second layer of 400 nm light-scattering anatase particles (CCIC, Japan). Detailed procedures for the preparation of TiO2 nanoparticles and pastes are reported elsewhere.42 A standard Z907 dye was used as the sensitizer with an addition of phenylpropionic acid as a cosolvent (1:1 ratio) in a solvent mixture of tert-butanol and acetonitrile (1:1 v/v ratio). The above-described double-layered TiO2 films were burnt for 30 min at 500 °C and immersed in the dye solution for 16 h. After sensitization, they were rinsed in pure MeCN and assembled with platinized counterelectrodes. The counter-electrodes were prepared using conducting glass TEC 15 (resistance 15Ω/cm², 2 mm thick) on which the drop of a solution of hexachloroplatinate acid in n-propanol was cast. Thermal platinization occurred while heating the electrodes twice for 15 min at 425 °C in the air. Electrodes were then sealed with a 25-μm-thick hot-melt film (Surlyn, Dupont) by heating the system at 100 °C. Devices were completed by filling the space between the electrodes with electrolyte through predrilled holes in the counter electrodes, and the holes were sealed with a Surlyn sheet and a thin glass cover by heating. Finally, metal contacts were placed on both electrodes.

Photovoltaic Measurements. Photovoltaic measurements were performed under simulated Sun irradiance (100 mW cm⁻², equivalent of 1 Sun at air mass global, AM 1.5G, at the surface of the device)
provided by a 450 W xenon light source (Oriel, USA). A Schott K113 Tempax sunlight filter (Präzision Glas & Optik GmbH, Germany) was used to correct the spectral output of the lamp in the region 350–750 nm. Current–voltage characteristics (in the dark and under illumination) were obtained by applying a forward potential bias and measuring resulting current with a Keithley 2400 digital sourcemeter (Keithley, USA). A metal mask was used to precisely define the irradiated surface area (0.159 cm²). Quantum efficiencies of the cells were measured by a similar data acquisition system. A Gemini-180 double monochromator (Jobin Yvon Ltd., UK) was used to separate the probing wavelength from the white light being shone by a 300 W xenon lamp (ILC Technology, USA). Measurements were conducted within the UV–vis range (350–850 nm, with a 10 nm interval).

Transient Photovoltage Decay Measurements. Transient decays were measured under white light bias with superimposed red light perturbation pulses (both light sources were LEDs). The voltage dynamics were recorded by using a Keithley 2400 source meter. Varying the intensity of white light bias allowed the recombination rate constant (and thus apparent electron lifetime) to be estimated at different open-circuit potentials by controlling the concentration of the free charges in TiO₂. Red perturbation pulses were adjusted to a very low level in order to maintain single-exponential voltage decay.

Electrochemical Measurements. Cyclic voltammetry and electrochemical impedance spectroscopy were used to determine diffusion coefficients of Jₐ of the electrolytes. The setup consisted of a Potentiostat/Galvanostat Model 273A (EG&G Princeton Applied Research, USA) and a 1250 Frequency Response Analyzer (Solartron Schlumberger, UK) controlled by CorrWare software (v. 3.2). Symmetric cells were employed with a 20-μm-thick layer of electrolyte encapsulated between two identical electrodes (FTO covered conductive glass TEC15 twice platinized with a solution of H₂PtCl₆ in n-propanol, at 450 °C for 15 min). A Surlin ring, which was used to seal the cell, determined the thickness of the electrolyte layer.

## ACKNOWLEDGMENTS

We thank EPFL and Swiss National Science Foundation for financial support. D.-R.Z. thanks the National Natural Science Foundation of China (No. 21171093) for financial support. M.G. thanks the Swiss National Science Foundation for the financial support under the Indo Swiss Joint Research Programme (ISJRP) grant. We thank Lonza AG for providing Na[A(CN)₃]₂ and Dr. Emil F. Aust, Merck KGaA, Germany for proving us with a sample of K[B(CN)₃]₂. We also thank Mr. Pascal Comte for providing us the mesoporous TiO₂ films.
