ABSTRACT

The efficient azidation of β-keto esters and silyl enol ethers using a benziodoxole-derived azide transfer reagent is reported. The azidation of cyclic β-keto esters could be achieved in up to quantitative yields in the absence of any catalyst. In the case of less reactive linear β-keto esters and silyl enol ethers, complete conversion and good yields could be obtained by using a zinc catalyst.

Azides are extremely useful functional groups in synthetic chemistry. They are easily reduced to amines, but are themselves non-basic. They consequently constitute ideal amine precursors in multi-step synthesis. Furthermore, cycloaddition of azides with alkynes, especially catalyzed by copper, has become the most impressive example of "Click" chemistry, as it is completely orthogonal to other functionalities and can run under mild conditions without the need to exclude oxygen or moisture. This reaction is now one of the most often used functionalization methods for biomolecules and polymers. In this context, new methods to introduce azides, especially in complex molecules, are urgently needed.

Most approaches to access azides are based on the use of nucleophilic sodium azide. In contrast, the introduction of azides onto nucleophiles is much less developed. Such reactions would be especially useful to access α-azido carbonyl compounds, which are important building

blocks in synthetic chemistry as precursors of amino acid derivatives. Sulfonyl azides have been most often used as electrophilic azide sources, but they work best for strongly nucleophilic lithium enolates. For the stabilized enolates derived from dicarbonyl compounds, a mixture of products resulting from competing diazo transfer and subsequent rearrangements has been observed. Another successful approach is based on the in situ Umpolung of either the azide or the enolate using a strong oxidant. These reactions often involve the formation of iodoazole or hypervalent iodine reagents, and have been usually proposed to proceed via a radical pathway. In the case of the azidation of dicarbonyl compounds, the most general protocol has been reported in 2012 by Kirsch and co-workers based on the combination of sodium azide and IBX. In most oxidative methods, the actual azidation reagent is either unknown, or so unstable that it cannot be isolated. This makes the development of catalytic or asymmetric methods very difficult. In fact, until 2013, no catalytic asymmetric α-azidation of carbonyl compounds had been reported, and the only method to access enantiopure products was based on a chiral auxiliary approach.

To solve this challenge, we decided to make use of the exceptional stability of benziodoxol(on)one-based hypervalent iodine reagents. Our group has recently demonstrated the exceptional properties of this class of reagents for acetylene transfer onto dicarbonyl compounds, and we wondered if similar azido reagents would be equally successful. In fact, Zhdkinkin and co-workers have described the synthesis of azido benziodoxol(on)one compounds, which were surprisingly stable. The reactivity of these reagents was studied for the radical-based azidation of aliphatic C-H bonds.

During completion of our work, Gade and co-workers reported the first catalytic asymmetric method for the azidation of β-keto esters and oxindoles using a chiral iron catalyst together with an azidobenziodoxole reagent. This major breakthrough motivate us to report our own preliminary results in the area, including the very efficient azidation of cyclic β-keto esters with azidobenziodoxole in the absence of any catalyst and the zinc-catalyzed azidation of less reactive linear keto esters and silyl enol ethers using the same reagent (Scheme 1). Our results demonstrated that the potential of azidobenziodoxole reagents as electrophilic azidation reagents is not limited to cyclic β-keto esters.

We started our studies with the investigation of the azidation of keto ester 1a with benziodoxo(on)e reagents 2 and 6. Whereas no reaction was observed with benzodioxolone 1, a complete conversion to azide 3a was observed with benziodoxole 2 in different solvents, with the best yield (82% by 1H NMR) obtained in toluene. The better result obtained with benziodoxole 2 is probably due to the higher basicity of the alcoholate generated after azide transfer.

With this extremely simple protocol for the azidation of keto esters in hand, we shortly investigated the scope of the reaction (Table 1). On a 0.40 mmol scale, azide 3a could be isolated in 94% yield (entry 1). The azidation

proceeded in good yields independent of the electronic properties of the substituent on the benzene ring of indanone (entries 2-4). More sterically hindered esters gave quantitative yields of azide (entries 5 and 6). Azidation of keto amide 1g was also possible in 67% yield (entry 7). Nevertheless, the reaction did not work for less reactive substrates, and no conversion was observed for both acyclic keto ester 1h (entry 8) or silyl enol ether 4a (entry 9).

*4 (0.1 mmol), 2 (0.13 mmol), catalyst (15 mol %), solvent (2 mL); Yield obtained by 1H NMR using 1,3,5-trimethoxybenzene as standard.*

On a 0.40 mmol scale, the azidation worked for silyl enol ethers derived from indanone and tetralone (Table 3, entries 1 and 2). Complete conversion was achieved in a few hours. The reaction could also be applied to the synthesis of tertiary azides (entries 3 and 4). The silyl enol ethers of acetophenone derivatives also worked in the reaction (entries 5-8), giving access to both primary and secondary azides. The azidation also proceeded well in presence of a thiophene heterocycle (entry 9).

At this point, we wondered if the zinc-catalyzed conditions could also be used to extend the scope of azidation for keto ester substrates. Indeed, acyclic keto ester 1h, which did not react in the presence of azidobenziodoxole 2 only, could be now azidated in 73% yield (Table 3, entry 10). The reaction was also successful for keto esters bearing a more functionalized benzene ring (entries 11 and 12) or a thiophene heterocycle (entry 13).
Cyclic keto esters are a privileged class of substrates for the development of asymmetric reactions, as two-point binding of a chiral catalyst can lead to good enantioselectivity. However, the high background rate observed with reagent 2 for cyclic keto esters constituted an important challenge for asymmetric induction. Nevertheless, an interesting preliminary result was obtained using a copper catalyst and bisoxazoline 7 as chiral ligand for the azidation of keto ester 1e with 49% ee (Scheme 3). The results of Gade and co-workers obtained simultaneously to our own investigations demonstrated the higher efficiency of a tridentate bisoxazoline ligand with iron as catalyst.11

^aIsolated yields with keto ester 1 or enol ether 4 (0.40 mmol), benziodoxole 2 (0.52 mmol), Zn(OTf)_2 (0.060-0.12 mmol), toluene (0.8 mL), 12 h at rt.

Several mechanisms can be envisaged for the azidation reaction. A first possibility is nucleophilic attack of either the oxygen or the carbon atom of the enolate on the iodine atom of benziodoxole 2, followed by C-N bond formation. A second alternative would involve a radical chain reaction, as has been proposed by Magnus and co-workers.6c-h However, several observations make the latter less probable: in contrast to what was reported by Magnus and co-workers, no reaction was observed in the absence of catalyst. Furthermore, diazidation products resulting from radical pathways were not obtained, and the reaction did not require the presence of a bulky triisopropylsilyl group on the oxygen. Finally, the addition of TEMPO to the reaction mixture had no influence on the reaction outcome, neither with keto esters nor with silyl enol ethers. These results are consequently more in accordance with an electrophilic azidation, as has been proposed recently by Muniz and co-workers for the transfer of NTs group using an hypervalent iodine reagent.14 The role of the zinc catalyst is also intriguing, as it may act either through nucleophilic activation by formation of a zinc enolate, or by electrophilic activation of benziodoxole 2. Further investigations will be required to gain a better understanding of the reaction mechanism.

In conclusion, we have described that the azidation of cyclic keto esters with benziodoxole reagent 2 proceeded in excellent yield in the absence of any catalyst. For less reactive acyclic keto esters and silyl enol ethers, an efficient zinc-catalyzed method could be developed, which gave access to primary, secondary and tertiary azides. Further extension of the scope of the reaction and development of asymmetric protocols not limited to

cyclic keto esters are currently under investigation and the results will be reported in due course.

1. General Methods

All reactions were carried out in oven dried glassware under an atmosphere of nitrogen, unless stated otherwise. For quantitative flash chromatography technical grade solvents were used. For flash chromatography for analysis, HPLC grade solvents from Sigma-Aldrich were used. THF, Et₂O, CH₃CN, toluene, hexane and CH₂Cl₂ were dried by passage over activated alumina under nitrogen atmosphere (H₂O content < 10 ppm, Karl-Fischer titration). All chemicals were purchased from Acros, Aldrich, Fluka, VWR, Fluorochem, Aplichem or Merck and used without further purification, unless stated otherwise. Chromatographic purification was performed as flash chromatography using Macherey-Nagel silica 40-63, 60 Å, using the solvents indicated as eluent with 0.1-0.5 bar pressure. TLC was performed on Merck silica gel 60 F₂₅₄ TLC aluminium plates and visualized with UV light and anisaldehyde stain. Melting points were measured on a calibrated Büchi B-540 melting point apparatus using open glass capillaries. ¹H-NMR spectra were recorded on a Bruker DPX-400 400 MHz spectrometer in chloroform-d and/or DMSO-d₆. All signals are reported in ppm with the internal chloroform signal at 7.26 ppm or the internal DMSO signal at 2.50 ppm as standard. The data is being reported as (s = singlet, d = doublet, t = triplet, q = quadruplet, qi = quintet, m = multiplet or unresolved, br = broad signal, app = apparent, coupling constant(s) in Hz, integration, interpretation). ¹³C-NMR spectra were recorded with ¹H-decoupling on a Bruker DPX-400 100 MHz spectrometer in chloroform-d and/or DMSO-d₆. All signals are reported in ppm with the internal chloroform signal at 77.0 ppm or the internal DMSO signal at 39.5 ppm as standard. Infrared spectra were recorded on a JASCO FT-IR B4100 spectrophotometer with an ATR PRO410-S and a ZnSe prisma and are reported as cm⁻¹ (w = weak, m = medium, s = strong, br = broad). Gas chromatographic and low resolution mass spectrometric measurements were performed on a Perkin-Elmer Clarus 600 gas chromatographer and mass spectrometer using a Perkin-Elmer Elite fused silica column (length: 30 m, diameter: 0.32 mm) and Helium as carrier gas. High resolution mass spectrometric measurements were performed by the mass spectrometry service of ISIC at the EPFL on a MICROMASS (ESI) Q-TOF Ultima API. Compound 7 was purchase from Aldritch.

2.1 Synthesis of 1-azido-3,3-dimethyl-3-(1H)-1,2-benziodoxole (2)

1-Chloro-1,3-dihydro-3,3-dimethyl-1,2-benziodoxole (9)

Following a reported procedure\(^1\) methyl 2-iodobenzoate (8) (12 mL, 76 mmol) was dissolved under N\(_2\) atmosphere in dry diethyl ether (400 mL) and then the solution was cooled down at 0 °C with an ice bath. Methylmagnesium bromide (56.0 mL, 168 mmol, 2.2 equiv) was added dropwise and the reaction was stirred for 30 min at 0 °C. The reaction mixture was then allowed to warm to room temperature and it was further stirred for 2 h. The reaction was quenched with NH\(_4\)Cl in an iced bath. The organic layer was separated and extracted with Et\(_2\)O (3 x 100 mL), water (2 x 200 mL), brine (1 x 100 mL) and the combined organic layers were dried over MgSO\(_4\). The solvent was removed in vacuum.

With no further purification the crude mixture was dissolved in CCl\(_4\) (7 mL) and tert-butyl hypochlorite (10 mL, 92 mmol, 1.2 equiv) and the reaction mixture was stirred at room temperature. After one hour a yellow precipitate was collected by filtration and washed with hexane (60 mL) to afford compound 9 (7.7 g, 26 mmol, 34% yield) as a yellow solid.

1-Acetoxy-1,3-dihydro-3,3-dimethyl-1,2-benziodoxole (10)

Following a reported procedure \(^1\) 1-Chloro-1,3-dihydro-3,3-dimethyl-1,2-benziodoxole (9) (2.60 g, 8.77 mmol) was dissolved in dry acetonitrile (25 mL) under N\(_2\) atmosphere. The reaction flask was covered with aluminum foils and protected from light. Silver acetate (1.46 g, 8.77 mmol, 1.00 equiv) was then added in one portion. The reaction mixture was stirred in the dark at room temperature for 16 h. Filtration over a Celite plug and evaporation of the solvent yielded compound 10 (2.6 g, 8.8 mmol, 93%) as a light brownish solid.

1-Acetoxy-1,2-benziodoxol-3-(1H)-one (13)

Following a reported procedure,⁴ compound 12 (3.00 g, 11.3 mmol, 1.0 equiv) was heated in Ac₂O (10 mL) to reflux until the solution turned clear (without suspension). The mixture was then left to cool down and white crystals started to form. The crystallization was continued at -18 °C. The crystal were then collected and dried overnight under high vacuum to give compound 13 (3.06 g, 10.0 mmol, 86%).

Synthesis of 1-azido-1,2-benziodoxole-3-(1H)-one (6)

Following a reported procedure,² compound 13 (1.00 g, 3.28 mmol, 1.0 equiv) was stirred in dry DCM (3 mL) then TMSN₃ (0.66 mL, 4.9 mmol, 1.5 equiv) was cautiously added. A catalytic amount of TMSOTf (3 µL, 0.02 mmol, 0.005 equiv) was added last to the mixture which was then stirred for 30 minutes. The reaction mixture was then died in vacuo to give a yellow precipitate, which was washed a few times with hexanes to give compound 6 (0.70 g, 2.4 mmol, 74%) as a pure pale yellow crystal.

3. Synthesis of starting materials

General procedure for the synthesis of β-keto esters.

Following a slightly modified procedure, a spatula of sodium tert-butoxide was added to a suspension of NaH (2.2 equiv) in dimethyl carbonate (5.0 equiv). The ketone (1 equiv) was then added carefully at 0 °C. The reaction was stirred at room temperature and followed by TLC (using the solvent mixture indicated below for the Rf value and UV or p-anisaldehyde for visualization). Then 1 M HCl was added until the pH of the solution became neutral or slightly acidic. The organic layers were collected and washed with brine (2 x 20 mL), dried over MgSO4 and concentrated in vacuum. The crude product was purified by column chromatography, using the solvent indicated for the Rf value.

Tert-butyl 1-oxo-1,2,3,4-tetrahydronaphthalene-2-carboxylate (15)

Compound 15 was synthetized following a reported procedure.α α-tetralone (13) (1.0 g, 6.8 mmol) in dry THF (5 mL) was added to a suspension of NaH (0.547 mg, 13.7 mmol, 2.00 equiv, 60% dispersion in mineral oil) in dry THF (25 mL) at rt. The solution was warmed to reflux and tert butyl pyrrole-1-carboxylate (14) (2.29 g, 13.7 mmol, 2.00 equiv) in dry THF (3 mL) was added dropwise and the solution was stirred at reflux until completion as indicated by TLC. After cooling to 0 °C, the solution was acidified with 1 N HCl. The solution was extracted with EtOAc (30 mL) and the organic layer was washed with brine (30 mL), dried (Na₂SO₄) and concentrated under reduced pressure. The residue was purified by flash silica gel chromatography (Rf: 0.3; 6:4 Pentane/ethylacetate).

Compound 17 was synthesized following a reported procedure.\textsuperscript{5} In a 50 mL flask, NaH (1.05 g, 26.2 mmol, 2.2 equiv) was suspended in THF (12 mL). Dimethyl carbonate (5.00 mL, 59.4 mmol, 5.00 equiv) was added to the mixture together with a catalytic amount of potassium tert-butoxide (67 mg, 0.59 mmol, 0.050 equiv). The solution was stirred for 1-2 minutes and then cyclopentanone (16) (1.0 g, 12 mmol) was added dropwise. The reaction was stirred at room temperature for 5 h. Water was then added carefully to quench the reaction. The aqueous layer was washed with Et\textsubscript{2}O (2 x 50 mL) and ethylacetate (2 x 50 mL). The organic layers were collected and washed with brine (2 x 50 mL). The solvent was evaporated under reduced pressure and the crude product was purified by flash chromatography (95:5 Pentane/ethylacetate) to give compound 17 (0.318 g, 2.24 mmol, 19%).

**General procedure for the synthesis of silyl enol ethers.**

The ketone (1.00 equiv) dissolved in anhydrous THF (0.33 M in ketone) was added in an oven-dried flask sealed with a septum and under N\(_2\) atmosphere. The solution was cooled down to 0°C and a 2 M solution of NaHMDS (1.22 eq) or freshly prepared LDA (1.05 equiv) was added dropwise. The cold bath is removed and the yellow solution was stirred for 1 hour at room temperature. The reaction was cooled again at 0°C and trimethyl silyl chloride (1.20 eq) was added dropwise. The reaction was stirred at room temperature for 5 hours after what the solvent was directly removed under reduced pressure. The resulting oil was purified by plug or by column chromatography on silica using the solvent indicated for the Rf value.

General procedure

Zn(OTf)$_2$ (0.021 g, 0.058 mmol, 0.030 equiv) was suspended in a 2 mL essay tube in toluene (0.5 M). The linear $\beta$-keto ester (1h-k) (0.40 mmol) was then added. The reaction mixture was stirred for one minute before adding in one portion the dimethyl azido benziodoxole 2 (0.15 g, 0.50 mmol, 1.3 equiv). The reaction was stirred at room and followed by TLC (using the solvent indicated for the $R_f$ value, visualization with UV or $p$-anisaldehyde stain) until complete consumption of the starting material (12-24 h). The crude mixture was purified by column chromatography, using the solvent indicated for the $R_f$ value.

The Lewis Acid (15 mol %) was suspended in a test tube of 2 mL in toluene (0.05 M). Silyl enol ether 4a-c (0.1 mmol) was added and the reaction was stirred for 1 minute. Then dimethyl azido benziodoxole 2 (0.13 mmol, 1.3 equiv) was added in one portion. The reaction was followed by TLC (using the solvent indicated for the Rf value, visualization with UV or p-anisaldehyde stain) until disappearance of the starting material. Without further purification a sample of 0.2 mL was dried under high vacuum. A known amount of trimethoxybenzene (1.7 mg, 0.010 mmol, external standard) was added to the crude mixture. The yield was determined by $^1$HNMR analysis comparison with 1,3,5-trimethoxybenzene peak at 6.2 ppm and the product peak at 4.32 ppm.

8. Enantioselective azidation of β-keto esters

Preparation of the complex.

CuCl$_2$ (2.0 mg, 0.015 mmol, 1.0 equiv) and (+)-2,2′-Isopropylidenebis[(4R)-4-benzyl-2-oxazoline] (5.3 mg, 0.015 mmol, 1.0 equiv) were stirred in a microwave tube of 2 mL in CH$_2$Cl$_2$ (0.5 mL) for 2 h. Then the solution was transferred into another microwave tube where AgSbF$_6$ (10 mg, 0.030 mmol, 2.05 equiv) was previously placed. The reaction was stirred at room temperature for 5 h. The mixture was filtered and the solvent evaporated. The resulting complex was stored in a dry box and used as soon as possible.

Enantioselective protocol.

A solution of reagent 2 (15 mg, 0.055 mmol, 1.3 equiv) in toluene (0.43 mL, 0.1 M in 1e) was added in a microwave tube of 2 mL to the preformed complex (5.7 mg, 6.0 $10^{-3}$ mmol, 0.014 equiv) and the starting material 1e (10 mg, 0.043 mmol). The reaction was stirred at room temperature and followed by TLC (using the solvent indicated for the R$_f$ value, visualization with UV or p-anisaldehyde stain) until disappearance of the starting material.

The solvent was removed by evaporation and the crude product was purified by flash chromatography (DCM/pentane 4:1) and product 3e (0.056 g, 0.21 mmol, 51% yield). A small sample of pure compound was analyzed by chiral HPLC: (IC, Hexane/PrOH = 99/1, 1 mL/min, 254nm), t$_R$(major isomer) = 11.8 min, t$_R$(minor isomer) = 13.3 min (49% ee).
