We consider the distance from a (square or rectangular) matrix pencil to the nearest matrix pencil in 2-norm that has a set of specified eigenvalues. We derive a singular value optimization characterization for this problem and illustrate its usefulness for two applications. First, the characterization yields a singular value formula for determining the nearest pencil whose eigenvalues lie in a specified region in the complex plane. For instance, this enables the numerical computation of the nearest stable descriptor system in control theory. Second, the characterization partially solves the problem posed in Boutry et al. (2005, SIAM J. Matrix Anal. Appl., 27, 582–601) regarding the distance from a general rectangular pencil to the nearest pencil with a complete set of eigenvalues. The involved singular value optimization problems are solved by means of Broyden-Fletcher-Goldfarb-Shanno and Lipschitz-based global optimization algorithms.

Keywords: matrix pencils; eigenvalues; optimization of singular values; inverse eigenvalue problems; Lipschitz continuity; Sylvester equation.

1. Introduction

Consider a matrix pencil \( A - \lambda B \), where \( A, B \in \mathbb{C}^{n \times m} \) with \( n \geq m \). Then, a scalar \( \rho \in \mathbb{C} \) is called an eigenvalue of the pencil if there exists a nonzero vector \( v \in \mathbb{C}^n \) such that

\[
(A - \rho B)v = 0. \tag{1.1}
\]

The vector \( v \) is said to be a (right) eigenvector associated with \( \rho \) and the pair \( (\rho, v) \) is said to be an eigenpair of the pencil.

In the square case \( m = n \), the eigenvalues are simply given by the roots of the characteristic polynomial \( \det(A - \lambda B) \) and there are usually \( n \) eigenvalues, counting multiplicities. The situation is quite
the opposite for \( n > m \). Generically, a rectangular pencil \( A - \lambda B \) has no eigenvalues at all. To see this, note that a necessary condition for the satisfaction of (1.1) is that \( n!/((n-m)!m!) \) polynomials, each corresponding to the determinant of a pencil obtained by choosing \( m \) rows of \( A - \lambda B \) out of \( n \) rows, must have a common root. Also, the generic Kronecker canonical form (KCF) of a rectangular matrix pencil only consists of singular blocks (see Demmel & Edelman, 1995). Hence, (1.1) is an ill-posed problem and requires reformulation before admitting numerical treatment.

To motivate our reformulation of (1.1), we describe a typical situation giving rise to rectangular matrix pencils. Let \( M \in \mathbb{C}^{n \times m} \) and suppose that the columns of \( U \in \mathbb{C}^{n \times m} \) form an orthonormal basis for a subspace \( \mathcal{W} \subset \mathbb{C}^n \) known to contain approximations to some eigenvectors of \( M \). Then, it is quite natural to consider the \( n \times m \) matrix pencil

\[
A - \lambda B := MU - \lambda U. \tag{1.2}
\]

The approximations contained in \( \mathcal{W} \) and the approximate eigenpairs of \( A - \lambda B \) are closely connected to each other. In one direction, suppose that \( (\rho, x) \) with \( x \in \mathcal{W} \) satisfies

\[
(M + \Delta M - \rho I)x = 0 \tag{1.3}
\]

for some (small) perturbation \( \Delta M \). Then there is \( v \in \mathbb{C}^n \) such that \( x = Uv \). Moreover, we have

\[
(A + \Delta A - \rho B)v = 0 \tag{1.4}
\]

with \( \Delta A := \Delta M \cdot U \) satisfying \( \| \Delta A \|_2 \leq \| \Delta M \|_2 \). In the other direction, the relation (1.4) with an arbitrary \( \Delta A \) implies (1.3) with \( \Delta M = \Delta A \cdot U^* \) satisfying \( \| \Delta M \|_2 = \| \Delta A \|_2 \). Unless \( M \) is normal, the first part of this equivalence between approximate eigenpairs of \( M \) and \( A - \lambda B \) does not hold when the latter is replaced by the more common compression \( U^*MU \). This observation has led to the use of rectangular matrix pencils in, e.g., large-scale pseudospectra computation (see Toh & Trefethen, 1996) and Ritz vector extraction (see Jia & Stewart, 2001).

This paper is concerned with determining the 2-norm distance from the pencil \( A - \lambda B \) to the nearest pencil \( (A + \Delta A) - \lambda B \) with a subset of specified eigenvalues. To be precise, let \( S = \{ \lambda_1, \ldots, \lambda_k \} \) be a set of distinct complex numbers and let \( r \) be a positive integer. Let \( m_j(A + \Delta A, B) \) denote the (possibly zero) algebraic multiplicity\(^1\) of \( \lambda_j \) as an eigenvalue of \( (A + \Delta A) - \lambda B \). Then, we consider the distance

\[
\inf \left\{ \| \Delta A \|_2 : \sum_{j=1}^k m_j(A + \Delta A, B) \geq r \right\}. \tag{1.5}
\]

1.1 **Rank-deficient \( B \)**

Throughout the paper, we allow \( B \) to be rank deficient. However, we require that \( \text{rank}(B) \geq r \). Otherwise, if \( \text{rank}(B) < r \), the pencil \( (A + \Delta A) - \lambda B \) has fewer than \( r \) finite eigenvalues for all \( \Delta A \) and, consequently, the distance in (1.5) is ill posed. As the following example demonstrates, another source of ill-posedness is the existence of a right singular block in the KCF of \( A - \lambda B \) or nearby pencils (see Section 2 on the KCF).

\(^1\) For a rectangular matrix pencil, the algebraic multiplicity of \( \lambda_j \) is defined as the sum of the sizes of associated regular Jordan blocks in the KCF; see also Section 2. By definition, this number is zero if \( \lambda_j \) is actually not an eigenvalue of the pencil.
Example 1.1 Consider the matrix pencil

\[ A - \lambda B = \begin{bmatrix} 2 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 1 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \]

which has the eigenvalues 2, 2, \( \infty \). Let \( S = \{0\} \) and \( r = 2 \), meaning that we aim at prescribing a multiple eigenvalue zero. In particular, \( A + \Delta A \) needs to be singular, implying that \( \| \Delta A \|_2 \geq 1 \). However, the perturbation

\[ \Delta A = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & -1 \end{bmatrix} \]

has norm 1 and results in a singular pencil, that is, \( \det(A + \Delta A - \lambda B) \equiv 0 \). Moreover, by an arbitrarily small additional perturbation, any two finite eigenvalues can be prescribed to the pencil. For example, with

\[ \tilde{\Delta} = \begin{bmatrix} 0 & 0 & (\lambda_1 - 2)\epsilon \\ (\lambda_2 - 2)\epsilon & 0 & -((\lambda_2 - 2)\epsilon^2) \\ -\epsilon^2 & \epsilon & \epsilon^3 \end{bmatrix}, \]

the pencil \( \det(A + \Delta A + \tilde{\Delta} - \lambda B) \equiv 0 \) has eigenvalues \( \{\lambda_1, \lambda_2\} \) for any \( \lambda_1, \lambda_2 \in \mathbb{C} \), no matter how small \( \epsilon > 0 \) is chosen. As discussed by De Terán & Kressner, in a paper in preparation, this observation holds in a more general setting: for any pencil \( A - \lambda B \) having a right singular block, there is an arbitrarily small perturbation prescribing up to rank(\( B \)) eigenvalues at any given locations.

Motivated by the observations in the example above, it appears to be more natural to replace (1.5) by the distance

\[ \tau_r(S) := \inf \left\{ \| \Delta A \|_2 : \sum_{j=1}^{k} m_j(A + \Delta A, B) \geq r \text{ or } A + \Delta A - \lambda B \text{ has a right singular block} \right\}. \] (1.6)

1.2 Relation to existing results

For \( k = r = 1 \), it is easy to see that

\[ \tau_1(\{\lambda_1\}) = \sigma_m(A - \lambda_1 B), \]

where, here and in the following, \( \sigma_k \) denotes the \( k \)th largest singular value of a matrix. (The particular form of this problem with \( k = r = 1 \), and when \( A \) and \( B \) are perturbed simultaneously, is also studied for instance in Byers & Nichols, 1993.) One of the main contributions of this paper is a derivation of a similar singular value optimization characterization for general \( k \) and \( r \), which facilitates the computation of \( \tau_r(S) \). Very little seems to be known in this direction. Existing results concern the square matrix case (\( m = n \) and \( B = I \)); see the works by Malyshev (1999) for \( k = 1 \) and \( r = 2 \) as well as Lippert (2005), Gracia (2005) for \( k = 2 \) and \( r = 2 \), Ikramov & Nazari (2003) for \( k = 1 \) and \( r = 3 \) and Mengi (2011) for \( k = 1 \) and arbitrary \( r \). Some attempts have also been made by Lippert (2010) for arbitrary \( k \) and \( r \) and for the square matrix case, and by Papathanasiou & Psarrakos (2008) for \( k = 1 \) and \( r = 2 \) and for the square matrix polynomial case.
Another class of applications arises in (robust) control theory, where it is desirable to move some or all eigenvalues into a certain region in the complex plane by perturbing a dynamical system. With the region of interest denoted by $\Omega \subseteq \mathbb{C}$, the results in this paper are an important step towards rendering the numerical computation of the distance
\[
\inf\{\|\Delta A\|_2 : (A + \Delta A) - \lambda B \text{ has } r \text{ finite eigenvalues in } \Omega\}
\]
feasible. Here and in the following, multiple eigenvalues are counted according to their algebraic multiplicities. For $r = 1$ and $\Omega$ equal to $\mathbb{C}^+$ (right-half complex plane), the quantity above amounts to the distance to instability, also called stability radius. In Van Loan (1984), a singular value characterization was provided for the distance to instability, forming the basis of a number of algorithms for its computation; see, e.g., Boyd & Balakrishnan (1990) and Byers (1988). In our more general setting, we can also address the converse problem: given an unstable matrix pencil $A - \lambda B$, determine the closest stable pencil. Note that this problem is intrinsically harder than the distance to instability. For the distance to instability it suffices to perturb the system so that one of the eigenvalues is in the undesired region. On the other hand, to make an unstable system stable one needs to perturb the system so that all eigenvalues lie in the region of stability.

An important special case, $\Omega = \mathbb{C}$, leads to
\[
\inf\{\|\Delta A\|_2 : (A + \Delta A) - \lambda B \text{ has } r \text{ finite eigenvalues}\}.
\]
For $r = 1$ and particular choices of rectangular $A$ and $B$, this distance corresponds to the distance to uncontrollability for a matrix pair (see Eising, 1984; Burke et al., 2005). For general $r$, a variant of this distance was suggested in Boutry et al. (2005) to solve an inverse signal processing problem approximately. More specifically, this problem is concerned with the identification of the shape of a region in the complex plane given the moments over the region. If the region is assumed to be a polygon, then its vertices can be posed as the eigenvalues of a rectangular pencil $A - \lambda B$, where $A$ and $B$ are not exact due to measurement errors, causing the pencil to have no eigenvalues (see Elad et al., 2004 for details). Then the authors attempt to locate nearby pencils with a complete set of eigenvalues. In this work, we allow perturbations to $A$ only, but not to $B$. This restriction is only justified if $\lambda$ does not become too large in absolute value. We consider our results and technique as significant steps towards the complete solution of the problem posed in Elad et al. (2004).

1.3 Outline

In the next section, we review the KCF for the pencil $A - \lambda B$. In Section 3, we derive a rank characterization for the condition that $\sum_{i=1}^k m_j(A, B) \geq r$ or $A - \lambda B$ has a right singular block. This is a crucial prerequisite for deriving the singular value characterizations of $\tau_r(S)$ in Section 4. In Section 5 we discuss several corollaries, in particular for the distances to pencils with eigenvalues in a prescribed region $\Omega$ and to rectangular pencils with a prescribed number of eigenvalues, of the singular value characterization for $\tau_r(S)$. The singular value characterizations are deduced under certain mild multiplicity and linear independence assumptions. Although we expect these assumptions to be satisfied for examples of practical interest, they may fail to hold, as demonstrated by an academic example in Section 6. Interestingly, the singular value characterization remains true for this example despite the fact that our derivation no longer applies. Finally, a numerical approach to solving the involved singular value optimization problems is briefly outlined in Section 7 and applied to a number of settings in Section 8.
The main point of the developed numerical method and the experiments is to demonstrate that the singular value characterizations facilitate the computation of $\tau_r(\mathbb{S})$ and related distances. We do not claim that the method outlined here is as efficient as it could be, neither do we claim that it is reliable.

2. Kronecker canonical form

Given a matrix pencil $A - \lambda B \in \mathbb{C}^{n \times m}$, the KCF (see Gantmacher, 1959) states the existence of invertible matrices $P \in \mathbb{C}^{n \times n}$ and $Q \in \mathbb{C}^{m \times m}$ such that the transformed pencil $P(A - \lambda B)Q$ is block diagonal with each diagonal block taking the form

$$J_p(\alpha) - \lambda I_p \quad \text{or} \quad I_p - \lambda J_p(0) \quad \text{or} \quad F_p - \lambda G_p \quad \text{or} \quad F_p^T - \lambda G_p^T,$$

where

$$J_p(\alpha) = \begin{bmatrix} \alpha & 1 & & & \\ & \alpha & \ddots & & \\ & & \ddots & 1 & \\ & & & \alpha & \\ p \times p \end{bmatrix}, \quad F_p = \begin{bmatrix} 1 & 0 & & & \\ & \ddots & \ddots & & \\ & & 1 & 0 & \\ p \times (p+1) \end{bmatrix}, \quad G_p = \begin{bmatrix} 0 & 1 & & & \\ & \ddots & \ddots & & \\ & & 0 & 1 & \\ p \times (p+1) \end{bmatrix}, \quad (2.1)$$

for some $\alpha \in \mathbb{C}$. Regular blocks take the form $J_p(\alpha) - \lambda I_p$ or $I_p - \lambda J_p(0)$, with $p \geq 1$, corresponding to finite or infinite eigenvalues, respectively. The blocks $F_p - \lambda G_p$ and $F_p^T - \lambda G_p^T$ are called right and left singular blocks, respectively, with $p \geq 0$ corresponding to a so-called Kronecker index.

3. Rank characterization for pencils with specified eigenvalues

In this section, we derive a rank characterization for the satisfaction of the condition

$$\sum_{j=1}^{k} m_j(A, B) \geq r \quad \text{or} \quad (A + \Delta A) - \lambda B \text{ has a right singular block}, \quad (3.1)$$

where $m_j(A, B)$ denotes the algebraic multiplicity of the eigenvalue $\lambda_j$. The following classical result (Gantmacher, 1959, Theorem 1, p. 219) concerning the dimension of the solution space for a Sylvester equation will play a central role.

**Theorem 3.1** Let $F \in \mathbb{C}^{m \times m}$ and $G \in \mathbb{C}^{r \times r}$. Then the dimension of the solution space for the Sylvester equation

$$FX - XG = 0$$

only depends on the Jordan canonical forms of the matrices $F$ and $G$. Specifically, suppose that $\mu_1, \ldots, \mu_\ell$ are the common eigenvalues of $F$ and $G$. Let $c_{j_1,1}, \ldots, c_{j_\ell,1}$ and $p_{l_1,1}, \ldots, p_{l_\ell,1}$ denote the sizes of the Jordan blocks of $F$ and $G$ associated with the eigenvalue $\mu_j$, respectively. Then

$$\dim\{X \in \mathbb{C}^{m \times r} : FX - XG = 0\} = \sum_{j=1}^{\ell} \sum_{i=1}^{\tilde{l}_j} \sum_{q=1}^{\tilde{p}_{i,q}} \min(c_{j,i}, p_{i,q}).$$
For our purposes, we need to extend the result of Theorem 3.1 to a generalized Sylvester equation of the form
\[ AX - BXC = 0, \]  
where \( C \) is a matrix with the desired set of eigenvalues \( \mathbb{S} \) and with the correct algebraic multiplicities. For this type of generalized Sylvester equation, the extension is straightforward.\(^2\) For the moment, let us suppose that \( A - \lambda B \) has no right singular block. Then, the KCF can be partitioned as
\[ P(A - \lambda B)Q = \text{diag}(A_F - \lambda I, I - \lambda A_I, A_S - \lambda B_S), \]  
such that
- \( A_F - \lambda I \) contains all regular blocks corresponding to finite eigenvalues;
- \( I - \lambda A_I \) contains all regular blocks corresponding to infinite eigenvalues;
- \( A_S - \lambda B_S \) contains all left singular blocks of the form \( F^T - \lambda G^T \).

Note that the finite eigenvalues of \( A - \lambda B \) are equal to the eigenvalues of \( A_F \) with the same algebraic and geometric multiplicities.

Using (3.3), \( X \) is a solution of the generalized Sylvester equation (3.2) if and only if
\[ (PAQ)(Q^{-1}X) = (PBQ)(Q^{-1}X)C = 0 \iff \text{diag}(A_F, I, A_S)Y - \text{diag}(I, A_I, B_S)YC = 0, \]  
where \( Y = Q^{-1}X \). Consequently, the dimension of the solution space for (3.2) is the sum of the solution space dimensions of the equations
\[ A_F Y_1 - Y_1 C = 0 \quad \text{and} \quad Y_2 - A_I Y_2 C = 0 \quad \text{and} \quad A_S Y_3 - B_S Y_3 C = 0. \]

Results by Demmel & Edelman (1995) show that the last two equations only admit the trivial solutions \( Y_2 = 0 \) and \( Y_3 = 0 \). To summarize, the solution spaces of the generalized Sylvester equation (3.2) and the (standard) Sylvester equation
\[ A_F X - XC = 0 \]  
have the same dimension. Applying Theorem 3.1, we therefore obtain the following result.

**Theorem 3.2** Let \( A, B \in \mathbb{C}^{n \times m} \) with \( n \geq m \) be such that the KCF of \( A - \lambda B \) does not contain right singular blocks. Then the dimension of the solution space for the generalized Sylvester equation
\[ AX - BXC = 0 \]  
only depends on the KCF of \( A - \lambda B \) and the Jordan canonical form of \( C \in \mathbb{C}^{r \times r} \). Specifically, suppose that \( \mu_1, \ldots, \mu_\ell \) are the common eigenvalues of \( A - \lambda B \) and \( C \). Let \( c_{j_1}, \ldots, c_{j_\ell} \) and \( p_{j_1}, \ldots, p_{j_\ell} \) denote the sizes of the Jordan blocks of \( A - \lambda B \) and \( C \) associated with the eigenvalue \( \mu_j \), respectively. Then
\[ \dim\{ X \in \mathbb{C}^{m \times r} : AX - BXC = 0 \} = \sum_{j=1}^{\ell} \sum_{i=1}^{\tilde{c}_j} \sum_{q=1}^{\tilde{p}_j} \min(c_{j_i}, p_{j_q}). \]

\(^2\) Košir (1996) provides an extension of Theorem 3.1 to a more general setting.
We now apply the result of Theorem 3.2 to the generalized Sylvester equation

\[ AX - BXC(\mu, \Gamma) = 0, \]

where \( C(\mu, \Gamma) \) takes the form

\[
C(\mu, \Gamma) = \begin{bmatrix}
\mu_1 & -\gamma_{21} & \cdots & -\gamma_{r1} \\
0 & \mu_2 & \cdots & \vdots \\
& \ddots & \ddots & \vdots \\
0 & & \ddots & -\gamma_{r,r-1} \\
& & & \mu_r
\end{bmatrix}
\]

(3.5)

with \( \mu = [\mu_1 \mu_2 \cdots \mu_r]^T \in \mathbb{S}^r, \quad \Gamma = [\gamma_{21} \gamma_{31} \cdots \gamma_{r,r-1}] \in \mathbb{C}^{(r-1)/2}. \)

As explained in the introduction, the set \( S = \{\lambda_1, \ldots, \lambda_k\} \) contains the desired approximate eigenvalues. Suppose that \( \lambda_j \) occurs \( p_j \) times in \( \mu \). Furthermore, as in Theorem 3.2, denote the sizes of the Jordan blocks of \( A - \lambda B \) and \( C(\mu, \Gamma) \) associated with the scalar \( \lambda_j \) by \( c_{j,1}, \ldots, c_{j,\ell_j} \) and \( p_{j,1}, \ldots, p_{j,\ell_j} \), respectively. Note that \( p_j = \sum_{q=1}^{\ell_j} p_{j,q} \). In fact, for generic values of \( \Gamma \) the matrix \( C(\mu, \Gamma) \) has at most one Jordan block of size \( p_j \) associated with \( \lambda_j \) for \( j = 1, \ldots, k \); see Demmel & Edelman (1995). In the following, we denote this set of generic values for \( \Gamma \) by \( \mathcal{G}(\mu) \). By definition, this set depends on \( \mu \) but not on \( A - \lambda B \).

First, suppose that the inequality in (3.1) holds. If we choose \( \mu \) such that \( \sum_{j=1}^k p_j = r \) and \( p_j \leq m_j(A, B) = \sum_{i=1}^{\ell_j} c_{j,i} \), then Theorem 3.2 implies that the dimension of the solution space for the generalized Sylvester equation (3.4) is

\[
\sum_{j=1}^k \sum_{i=1}^{\ell_j} \sum_{q=1}^{\ell_j} \min(c_{j,i}, p_{j,q}) \geq \sum_{j=1}^k \sum_{i=1}^{\ell_j} \min(c_{j,i}, p_j) \geq \sum_{j=1}^k \min(m_j(A, B), p_j) = \sum_{j=1}^k p_j = r.
\]

In other words, there exists a vector \( \mu \) with components from \( S \) such that the dimension of the solution space of the Sylvester equation (3.4) is at least \( r \).

Now, on the contrary, suppose that the inequality in (3.1) does not hold. Then, for generic values \( \Gamma \in \mathcal{G}(\mu) \), the solution space dimension of (3.4) is

\[
\sum_{j=1}^k \sum_{i=1}^{\ell_j} \min(c_{j,i}, p_j) \leq \sum_{j=1}^k \sum_{i=1}^{\ell_j} c_{j,i} = \sum_{j=1}^k m_j(A, B) < r.
\]

In other words, no matter how \( \mu \) is formed from \( S \), the dimension is always less than \( r \) for \( \Gamma \in \mathcal{G}(\mu) \). This leads to the following result.

**Theorem 3.3** Let \( A, B \in \mathbb{C}^{n \times m} \) with \( n \geq m \). Consider a set \( S = \{\lambda_1, \ldots, \lambda_k\} \) of distinct complex scalars, and a positive integer \( r \). Then the following two statements are equivalent:

1. \( \sum_{j=1}^k m_j(A, B) \geq r \), where \( m_j(A, B) \) is the algebraic multiplicity of \( \lambda_j \) as an eigenvalue of \( A - \lambda B \), or \( A - \lambda B \) has a right singular block;
\( \) there exists \( \mu \in \mathbb{S}' \) such that
\[
\dim \{ X \in \mathbb{C}^{m \times r} : AX - BXC(\mu, \Gamma) = 0 \} \geq r
\]
for all \( \Gamma \in \mathcal{G}(\mu) \), where \( C(\mu, \Gamma) \) is defined as in (3.5).

**Proof.** If the KCF of \( A - \lambda B \) does not contain right singular blocks, then the result follows from the discussion above. Now, suppose that the KCF of \( A - \lambda B \) contains a right singular block \( F_p - \lambda G_p \in \mathbb{R}^{p \times (p+1)} \) for some \( p \geq 0 \). By Košir (1996, Section 4), the generalized Sylvester equation \( F_p Y - G_p XC(\mu, \Gamma) = 0 \) has a solution space of dimension \( r \). This implies that also the solution space of \( AX - BXC(\mu, \Gamma) = 0 \) has dimension at least \( r \). This shows that (1) implies (2). The other direction trivially holds. \( \square \)

To obtain a matrix formulation of Theorem 3.3, we use the Kronecker product \( \otimes \) to vectorize the generalized Sylvester equation (3.4) and obtain
\[
( (I \otimes A) - (C^T(\mu, \Gamma) \otimes B) ) = \mathcal{L}(\mu, \Gamma, A, B) \text{vec}(X) = 0,
\]
with the lower block-triangular matrix
\[
\mathcal{L}(\mu, \Gamma, A, B) := \begin{bmatrix}
A - \mu_1 B & \gamma_{21} B & A - \mu_2 B \\
\vdots & \ddots & \ddots \\
\gamma_{r1} B & \cdots & A - \mu_{r-1} B & \gamma_{r2} B \\
\end{bmatrix}.
\]

The operator vec stacks the columns of a matrix into one long vector. Clearly, the solution space of the generalized Sylvester equation and the null space of \( \mathcal{L}(\mu, \Gamma, A, B) \) have the same dimension. Consequently, Theorem 3.3 can be rephrased as follows.

**Corollary 3.4** Under the assumptions of Theorem 3.3, the following two statements are equivalent:

1. \( \sum_{\lambda_j} m_j(A, B) \geq r \) or \( A - \lambda B \) has a right singular block;
2. there exists \( \mu \in \mathbb{S}' \) such that \( \text{rank}(\mathcal{L}(\mu, \Gamma, A, B)) \leq mr - r \) for all \( \Gamma \in \mathcal{G}(\mu) \).

**4. A singular value characterization for the nearest pencil with specified eigenvalues**

As before, let \( \mathbb{S} = \{\lambda_1, \ldots, \lambda_k\} \) be a set of distinct complex scalars and let \( r \) be a positive integer. The purpose of this section is to derive a singular value optimization characterization for the distance \( \tau_\tau(\mathbb{S}) \) defined in (1.6). Our technique is highly inspired by the techniques in Mengi (2011, 2012) and in fact the main result of this section generalizes the singular value optimization characterizations from these works. We start by applying the following elementary result (Golub & Van Loan, 1996, Theorem 2.5.3, p. 72) to the rank characterization derived in the previous section.

**Lemma 4.1** Consider \( C \in \mathbb{C}^{\ell \times q} \) and a positive integer \( p < \min(\ell, q) \). Then
\[
\inf\{ \| \Delta C \|_2 : \text{rank}(C + \Delta C) \leq p \} = \sigma_{p+1}(C).
\]
Defining
\[ P_r(\mu) := \inf \{ \| \Delta A \|_2 : \text{rank}(L(\mu, \Gamma, A + \Delta A, B)) \leq mr - r \} \] (4.1)
for some \( \Gamma \in \mathcal{G}(\mu) \), Corollary 3.4 implies
\[ \tau_r(S) = \inf_{\mu \in S} P_r(\mu), \]
and independent of the choice of \( \Gamma \). By Lemma 4.1, it holds that
\[ P_r(\mu) = \inf \{ \| \Delta A \|_2 : \text{rank}(L(\mu, \Gamma, A + \Delta A, B)) \leq mr - r \} \geq \sigma_{mr-r+1}(L(\mu, \Gamma, A, B)), \]
using the fact that \( A \) enters \( L \) linearly. Note that this inequality in general is not an equality due to the fact that the allowable perturbations to \( L(\mu, \Gamma, A, B) \) in the definition of \( P_r(\mu) \) are not arbitrary. On the other hand, the inequality holds for all \( \Gamma \in \mathcal{G}(\mu) \) and hence—by continuity of the singular value \( \sigma_{mr-r+1}(\cdot) \) with respect to \( \Gamma \)—we obtain the lower bound
\[ P_r(\mu) \geq \sup_{\Gamma \in \mathcal{G}(\mu)} \sigma_{mr-r+1}(L(\mu, \Gamma, A, B)) =: \kappa_r(\mu). \] (4.2)
For \( m = n \), it can be shown that \( \sigma_{mr-r+1}(L(\mu, \Gamma, A, B)) \) tends to zero \( \| \Gamma \| := \sum |\gamma_{ij}|^2 \to \infty \), provided that \( \text{rank}(B) \geq r \); see Appendix for details. From this fact and the continuity of singular values, it follows that the supremum is attained at some \( \Gamma_\ast \) in the square case:
\[ \kappa_r(\mu) = \sigma_{mr-r+1}(L(\mu, \Gamma_\ast, A, B)). \]
In the rectangular case, numerical experiments indicate that the supremum is still attained if \( \text{rank}(B) \geq r \), but a formal proof does not appear to be easy. Moreover, it is not clear whether the supremum is attained at a unique \( \Gamma_\ast \) or not. However, as we will show in the next two subsections, any local extremum of the singular value function is a global maximizer under mild assumptions. (To be precise, the satisfaction of the multiplicity and linear independence qualifications at a local extremum guarantees that the local extremum is a global maximizer; see Definitions 4.2 and 4.3 for multiplicity and linear independence qualifications."

Throughout the rest of this section we assume that the supremum is attained at some \( \Gamma_\ast \) and that \( \Gamma_\ast \in \mathcal{G}(\mu) \). The latter assumption will be removed later, in Section 4.3.

We will establish the reverse inequality \( P_r(\mu) \leq \kappa_r(\mu) \) by constructing an optimal perturbation \( \Delta A_\ast \) such that
\begin{itemize}
  \item[(i)] \( \| \Delta A_\ast \|_2 = \kappa_r(\mu) \) and
  \item[(ii)] \( \text{rank}(L(\mu, \Gamma_\ast, A + \Delta A_\ast, B)) \leq mr - r \).
\end{itemize}
Let us consider the left and right singular vectors \( U \in \mathbb{C}^n \) and \( V \in \mathbb{C}^m \) satisfying the relations
\[ L(\mu, \Gamma_\ast, A, B) V = \kappa_r(\mu) U, \quad U^* L(\mu, \Gamma_\ast, A, B) = V^* \kappa_r(\mu), \quad \| U \|_2 = \| V \|_2 = 1. \] (4.3)
The aim of the next two subsections is to show that the perturbation
\[ \Delta A_\ast := -\kappa_r(\mu) U V^+, \] (4.4)
with $U \in \mathbb{C}^{n \times r}$ and $V \in \mathbb{C}^{m \times r}$ such that $\text{vec}(U) = U$ and $\text{vec}(V) = V$, satisfies properties (i) and (ii). Here, $V^+$ denotes the Moore–Penrose pseudoinverse of $V$. The optimality of $\Delta A_\ast$ will be established under the following additional assumptions.

**Definition 4.2 (Multiplicity qualification)** We say that the multiplicity qualification holds at $(\mu, \Gamma)$ for the pencil $A - \lambda B$ if the multiplicity of the singular value $\sigma_{mr-r+1}(\mathcal{L}(\mu, \Gamma, A, B))$ is 1.

**Definition 4.3 (Linear independence qualification)** We say that the linear independence qualification holds at $(\mu, \Gamma)$ for the pencil $A - \lambda B$ if there is a right singular vector $V$ associated with $\sigma_{mr-r+1}(\mathcal{L}(\mu, \Gamma, A, B))$ such that $V \in \mathbb{C}^{m \times r}$, with $\text{vec}(V) = V$, has full column rank.

### 4.1 The 2-norm of the optimal perturbation

Throughout this section we assume that the multiplicity qualification holds at the optimal $(\mu, \Gamma_\ast)$ for the pencil $A - \lambda B$. Moreover, we can restrict ourselves to the case $\kappa_r(\mu) \neq 0$, as the optimal perturbation is trivially given by $\Delta A_\ast = 0$ when $\kappa_r(\mu) = 0$.

Let $\mathcal{A}(\gamma)$ be a matrix-valued function depending analytically on a parameter $\gamma \in \mathbb{R}$. If the multiplicity of $\sigma_j(\mathcal{A}(\gamma_\ast))$ is 1 and $\sigma_j(\mathcal{A}(\gamma_\ast)) \neq 0$, then $\sigma_j(\mathcal{A}(\gamma))$ is analytic at $\gamma = \gamma_\ast$, with the derivative

$$\frac{\partial \sigma_j(\mathcal{A}(\gamma_\ast))}{\partial \gamma} = \text{Re} \left( u_j^T \frac{\partial \mathcal{A}(\gamma_\ast)}{\partial \gamma} v_j \right),$$

where $u_j$ and $v_j$ denote a consistent pair of unit left and right singular vectors associated with $\sigma_j(\mathcal{A}(\gamma_\ast))$; see, e.g., Rellich (1936), Bunse-Gerstner et al. (1991) and Malyshev (1999).

Let us now define

$$f(\Gamma) := \sigma_{mr-r+1}(\mathcal{L}(\mu, \Gamma, A, B)),$$

where we view $f$ as a mapping $\mathbb{R}^{r(r-1)} \to \mathbb{R}$ by decomposing each complex parameter $\gamma_{j\ell}$ contained in $\Gamma$ into its real and imaginary parts $\Re \gamma_{j\ell}$ and $\Im \gamma_{j\ell}$. By (4.5), we have

$$\frac{\partial f(\Gamma_\ast)}{\partial \Re \gamma_{j\ell}} = \text{Re}(U_j^* B V_{j\ell}), \quad \frac{\partial f(\Gamma_\ast)}{\partial \Im \gamma_{j\ell}} = \text{Re}(i U_j^* B V_{j\ell}) = -\text{Im}(U_j^* B V_{j\ell}),$$

where $U_j \in \mathbb{C}^n$ and $V_{j\ell} \in \mathbb{C}^m$ denote the $j$th and $\ell$th block components of $U$ and $V$, respectively. Furthermore, the fact that $\Gamma_\ast$ is a global maximizer of $f$ implies that both derivatives are zero. Consequently, we obtain the following result.

**Lemma 4.4** Suppose that the multiplicity qualification holds at $(\mu, \Gamma_\ast)$ for the pencil $A - \lambda B$ and $\kappa_r(\mu) \neq 0$. Then, $U_j^* B V_{j\ell} = 0$ for all $j = 2, \ldots, r$ and $\ell = 1, \ldots, j - 1$.

Now, by exploiting Lemma 4.4 we show $U^* U = V^* V$. Geometrically, this means that the angle between $U_i$ and $U_j$ is identical with the angle between $V_i$ and $V_j$. 
Lemma 4.5 Under the assumptions of Lemma 4.4 it holds that $U^*U = \mathcal{V}^*\mathcal{V}$.

Proof. Expressing the first two equalities in the singular value characterization (4.3) in matrix form yields the generalized Sylvester equations

\[ A\mathcal{V} - BVC(\mu, \Gamma_\sigma) = \kappa_r(\mu)U \]

and

\[ U^*A - C(\mu, \Gamma_\sigma)U^*B = \kappa_r(\mu)V. \]

By multiplying the first equation with $U^*$ from the left-hand side, multiplying the second equation with $V$ from the right-hand side and then subtracting the second equation from the first, we obtain

\[ \kappa_r(\mu)(U^*U - V^*V) = C(\mu, \Gamma_\sigma)U^*B - U^*BVC(\mu, \Gamma_\sigma). \tag{4.6} \]

Lemma 4.4 implies that $U^*B\mathcal{V}$ is upper triangular. Since $C(\mu, \Gamma_\sigma)$ is also upper triangular, the right-hand side in (4.6) is strictly upper triangular. But the left-hand side in (4.6) is Hermitian, implying that the right-hand side is indeed zero, which—together with $\kappa_r(\mu) \neq 0$—completes the proof. □

The result of Lemma 4.5 implies $\|U\mathcal{V}\|_2 = 1$. A formal proof of this implication can be found in Malyshev (1999, Lemma 2) and Mengi (2011, Theorem 2.5). Indeed, the equality $\|U\mathcal{V}\|_2 = 1$ can be directly deduced from $\|U\mathcal{V}x\|_2 = \|\mathcal{V}^+x\|_2$ for every $x$ (implied by Lemma 4.5), and $\|\mathcal{V}^+\|_2 = 1$ (since $\mathcal{V}^+$ is an orthogonal projector).

Theorem 4.6 Suppose that the multiplicity qualification holds at $(\mu, \Gamma_\sigma)$ for the pencil $A - \lambda B$. Then the perturbation $\Delta A_\sigma$ defined in (4.4) satisfies $\|\Delta A_\sigma\|_2 = \kappa_r(\mu)$.

4.2 Satisfaction of the rank condition by the optimally perturbed pencil

Now we assume that the linear independence qualification (Definition 4.3) holds at $(\mu, \Gamma_\sigma)$ for the pencil $A - \lambda B$. In particular, we assume that we can choose a right singular ‘vector’ $\text{vec}(\mathcal{V})$ so that $\mathcal{V}$ has full column rank. We will establish that

\[ \text{rank}(\mathcal{L}(\mu, \Gamma_\sigma, A + \Delta A_\sigma, B)) \leq mr - r \tag{4.7} \]

for $\Delta A_\sigma$ defined as in (4.4).

Writing the first part of the singular vector characterization (4.3) in matrix form leads to the generalized Sylvester equation

\[ A\mathcal{V} - BVC(\mu, \Gamma_\sigma) = \kappa_r(\mu)U. \]

The fact that $\mathcal{V}$ has full column rank implies $\mathcal{V}^+\mathcal{V} = I$ and hence

\[ A\mathcal{V} - BVC(\mu, \Gamma_\sigma) = \kappa_r(\mu)U\mathcal{V}^+\mathcal{V}, \]

\[ \implies (A - \kappa_r(\mu)U\mathcal{V}^+)\mathcal{V} - BVC(\mu, \Gamma_\sigma) = 0, \]

\[ \implies (A + \Delta A_\sigma)\mathcal{V} - BVC(\mu, \Gamma_\sigma) = 0. \]

Let us consider $\mathcal{M} = \{D \in \mathbb{C}^{r \times r} : C(\mu, \Gamma_\sigma)D - DC(\mu, \Gamma_\sigma) = 0\}$, the subspace of all $r \times r$ matrices commuting with $C(\mu, \Gamma_\sigma)$. By Theorem 3.1, $\mathcal{M}$ is a subspace of dimension at least $r$. Clearly, for all $D \in \mathcal{M}$,
we have
\[ 0 = (A + \Delta A_s)VD - BYC(\mu, \Gamma_s)D = (A + \Delta A_s)(VD) - B(VD)C(\mu, \Gamma_s). \]
In other words, \[\{VD : D \in M\}\] has dimension at least \(r\) (using the fact that \(V\) has full column rank) and represents a subspace of solutions to the generalized Sylvester equation
\[ (A + \Delta A_s)X - BXC(\mu, \Gamma_s) = 0. \]
Reinterpreting this result in terms of the matrix representation, the desired rank estimate \((4.7)\) follows. This completes the derivation of \(\mathcal{P}_r(\mu) \leq \kappa_r(\mu)\) under the stated multiplicity and linear independence assumptions.

### 4.3 Main result

To summarize the discussion above, we have obtained the singular value characterization
\[ \tau_r(\mathcal{S}) = \inf_{\mu \in \mathcal{S}} \sup_{\Gamma} \sigma_{mr-r+1}(\mathcal{L}(\mu, \Gamma, A, B)). \quad (4.8) \]

Among our assumptions, we have
\[ \Gamma_s \in \mathcal{G}(\mu). \quad (4.9) \]
It turns out that this particular assumption can be dropped. To see this, we first note that both \(\mathcal{P}_r(\mu)\) and \(\kappa_r(\mu)\), defined in \((4.1)\) and \((4.2)\), change continuously with respect to \(\mu\). Suppose that \(\mu\) has repeating elements, which allows for the possibility that \(\Gamma_s \notin \mathcal{G}(\mu)\). But for all \(\tilde{\mu}\) with distinct elements, we necessarily have \(\mathcal{G}(\tilde{\mu}) = \mathbb{C}^{(r-1)/2}\). Moreover, when \(\tilde{\mu}\) is sufficiently close to \(\mu\), then \(\mathcal{P}_r(\tilde{\mu}) = \kappa_r(\tilde{\mu})\), provided that the multiplicity and linear independence assumptions hold at \((\mu, \Gamma_s)\) (implying the satisfaction of these two assumptions for \(\tilde{\mu}\) also). Then, the equality \(\mathcal{P}_r(\mu) = \kappa_r(\mu)\) follows from continuity. Consequently, the assumption \((4.9)\) is not needed for the singular value characterization. Note that this continuity argument depends on the attainment of the supremum in \((4.8)\) not only for \(\mu\), say at \(\Gamma_s\), but also for nearby \(\tilde{\mu}\). This can be ensured by the condition \(\sigma_{mr-r+1}(\mathcal{L}(\mu, \Gamma_s, A, B)) > \lim_{k \to \infty} \sigma_{mr-r+1}(\mathcal{L}(\mu, \Gamma_k, A, B))\) for any sequence \(\{\Gamma_k\}\) with \(\|\Gamma_k\| \to \infty\) as \(k \to \infty\). This is certainly true in the square case, as the singular value \(\sigma_{mr-r+1}(\mathcal{L}(\mu, \Gamma, A, B))\) decays to zero as \(\|\Gamma\| \to \infty\) as shown in the Appendix.

We conclude this section by stating the main result of this paper.

**Theorem 4.7 (Nearest pencils with specified eigenvalues)** Let \(A - \lambda B\) be an \(n \times m\) pencil with \(n \geq m\), let \(r\) be a positive integer and let \(\mathcal{S} = \{\lambda_1, \ldots, \lambda_k\}\) be a set of distinct complex scalars.

(i) Then
\[ \tau_r(\mathcal{S}) = \inf_{\mu \in \mathcal{S}} \sup_{\Gamma} \sigma_{mr-r+1}(\mathcal{L}(\mu, \Gamma, A, B)) \]
holds, provided that the optimization problem on the right is attained at some \((\mu_s, \Gamma_s)\) for which \(\Gamma_s\) is finite and such that \(\sigma_{mr-r+1}(\mathcal{L}(\mu_s, \Gamma_s, A, B)) > \lim_{k \to \infty} \sigma_{mr-r+1}(\mathcal{L}(\mu_s, \Gamma_k, A, B))\) for any sequence \(\{\Gamma_k\}\) with \(\|\Gamma_k\| \to \infty\) as \(k \to \infty\), and the multiplicity as well as the linear independence qualifications hold.

(ii) A minimal perturbation \(\Delta A_s\), such that \(\sum_{j=1}^k m(A + \Delta A_s, B) \geq r\) or \(A + \Delta A_s - \lambda B\) has a right singular block, is given by \((4.4)\), with \(\mu\) replaced by \(\mu_s\).
5. Corollaries of Theorem 4.7

As discussed in the introduction, one potential application of Theorem 4.7 is in control theory, to ensure that the eigenvalues lie in a particular region in the complex plane. Thus, let \( \Omega \) be a subset of the complex plane. Then, provided that the assumptions of Theorem 4.7 hold, we have the following singular value characterization for the distance to the nearest pencil with \( r \) eigenvalues in \( \Omega \):

\[
\tau_r(\Omega) := \inf \{ \| \Delta A \|_2 : (A + \Delta A) - \lambda B \text{ has } r \text{ finite eigenvalues in } \Omega \text{ or } (A + \Delta A) - \lambda B \text{ has a right singular block} \}
\]

where \( \Omega' \) denotes the set of vectors of length \( r \) with all entries in \( \Omega \).

When the pencil \( A - \lambda B \) is rectangular, that is, \( n > m \), the pencil has generically no eigenvalues. Then, the distance to the nearest rectangular pencil with \( r \) eigenvalues is of interest. In this case, the singular value characterization takes the following form:

\[
\tau_r(C) := \inf \{ \| \Delta A \|_2 : (A + \Delta A) - \lambda B \text{ has } r \text{ finite eigenvalues} \text{ or } (A + \Delta A) - \lambda B \text{ has a right singular block} \}
\]

The optimal perturbations \( \Delta A_* \) such that the pencil \( (A + \Delta A_*) - \lambda B \) has eigenvalues (in \( C \) and \( \Omega \)) are given by (4.4), with \( \mu \) replaced by the minimizing \( \mu \) values in (5.2) and (5.1), respectively.

6. Multiplicity and linear independence qualifications

The results in this paper are proved under the assumptions of multiplicity and linear independence qualifications. This section provides an example for which the multiplicity and linear independence qualifications are not satisfied for the optimal value of \( \Gamma \). Note that this does not mean that these assumptions are necessary to prove the results from this paper. In fact, numerical experiments suggest that our results may hold even if these assumptions are not satisfied.

Consider the pencil

\[
\begin{bmatrix}
-1 & 0 & 0 \\
0 & 5 & 0 \\
0 & 0 & 2
\end{bmatrix} - \lambda \begin{bmatrix}
0 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1
\end{bmatrix}.
\]

Let \( \mu = [5 \ 1]^T \), that is, the target eigenvalues are 5 and 1. Then, it is easy to see that the optimal perturbation is given by

\[
\Delta A_* = \begin{bmatrix}
0 & 0 & 0 \\
0 & 0 & 0 \\
0 & 0 & -1
\end{bmatrix}.
\]
The singular values of the matrix $L(\mu, \gamma, A, B)$ are

$$0, 1, \sqrt{16 + |\gamma|^2}, \sqrt{5 + \frac{1}{2}|\gamma|^2 \pm \frac{1}{2}\sqrt{|\gamma|^4 + 20|\gamma|^2 + 64}},$$

where the multiplicity of the singular value 1 is 2. Hence,

$$\sigma_5(L(\mu, \gamma, A, B)) = \sqrt{5 + \frac{1}{2}|\gamma|^2 \pm \frac{1}{2}\sqrt{|\gamma|^4 + 20|\gamma|^2 + 64}}.$$ 

Clearly, the supremum is attained for $\gamma = 0$ and $\sigma_5(L(\mu, 0, A, B)) = 1$. Hence, the multiplicity condition at the optimal $\gamma$ is violated. All three pairs of singular vectors corresponding to the singular value 1 at the optimal $\gamma$ violate the linear independence condition, but one pair does lead to the optimal perturbation $\Delta A$. 

7. Computational issues

A numerical technique that can be used to compute $\tau_r(\Omega)$ and $\tau_r(C)$ based on the singular value characterizations has already been described in Mengi (2011, 2012). For completeness, we briefly recall this technique in the following. The distances of interest can be characterized as

$$\tau_r(\Omega) = \inf_{\mu \in \Omega} g(\mu) \quad \text{and} \quad \tau_r(C) = \inf_{\mu \in C} g(\mu),$$

where $g : C^n \to \mathbb{R}$ is defined by

$$g(\mu) := \sup_{\Gamma \in C^n} \sigma_{nr+r+1}(L(\mu, \Gamma, A, B)).$$

The inner maximization problems are solved by Broyden-Fletcher-Goldfarb-Shanno (BFGS), even though $\sigma_{nr+r+1}(\cdot)$ is not differentiable at multiple singular values. In practice, this is not a major issue for BFGS as long as a proper line search respecting weak Wolfe conditions is used, since for any given $\mu$ a point $\Gamma$, where the singular value $\sigma_{nr+r+1}(L(\mu, \Gamma, A, B))$ is multiple, is isolated in $C^{n(n-1)/2}$; see the discussions in Lewis & Overton (2012). If the multiplicity and linear independence qualifications hold at a local maximizer $\Gamma^*$, then $\Gamma^*$ is in fact a global maximizer and hence $g(\mu)$ is retrieved. If, on the other hand, BFGS converges to a point where one of these qualifications is violated, it needs to be restarted with a different initial guess. In practice, we usually observe convergence to a global maximizer immediately, without the need for such a restart.

Although the function $g(\mu)$ is in general nonconvex, it is Lipschitz continuous:

$$|g(\mu + \delta \mu) - g(\mu)| \leq \|\delta \mu\|_2 \cdot \|B\|_2.$$ 

There are various Lipschitz-based global optimization algorithms in the literature stemming mainly from ideas due to Piyavskii and Shubert (see Piyavskii, 1972; Shubert, 1972). The Piyavskii–Shubert algorithm is based on the idea of constructing a piecewise linear approximation lying beneath the Lipschitz function. We used DIRECT (see Jones et al., 1993), a sophisticated variant of the Piyavskii–Shubert algorithm. DIRECT attempts to estimate the Lipschitz constant locally, which can possibly speed up convergence.

The main computational cost involved in the numerical optimization of singular values is the retrieval of the $r$th smallest singular value of $L(\mu, \Gamma, A, B)$ at various values of $\mu$ and $\Gamma$. As we only experimented with small pencils, we used direct solvers for this purpose. For medium- to large-scale
pencils, iterative algorithms such as the Lanczos method (see Golub & Van Loan, 1996) are more appropriate.

8. Numerical experiments

Our algorithm is implemented in Fortran and calls LAPACK routines for singular value computations. The limited memory BFGS routine written by J. Nocedal (discussed in Liu & Nocedal, 1989) is used for the inner maximization problems, and an implementation of the DIRECT algorithm by Gablonsky (described in Gablonsky, 2001) is used for the outer Lipschitz-based minimization. A MEX interface provides convenient access via MATLAB.

The current implementation is not very reliable, which appears to be related to the numerical solution of the outer Lipschitz minimization problem, in particular, the DIRECT algorithm and its termination criteria. We rarely obtain results that are less accurate than the prescribed accuracy. The multiplicity and linear independence qualifications usually hold in practice and do not appear to affect the numerical accuracy. For the moment, the implementation is intended for small pencils (e.g., \( n, m < 100 \)).

8.1 Nearest pencils with multiple eigenvalues

As a corollary of Theorem 4.7 it follows that, for a square pencil \( A - \lambda B \), the nearest pencil having \( S = \{ \mu \} \) as a multiple eigenvalue is given by

\[
\tau_2(S) = \sup_\gamma \left( \begin{bmatrix} A - \mu B & 0 \\ \gamma B & A - \mu B \end{bmatrix} \right),
\]

provided that the multiplicity and linear independence qualifications are satisfied at the optimal \((\mu, \gamma_\ast)\). Therefore, for the distance from \( A - \lambda B \) to the nearest square pencil with a multiple eigenvalue, the singular value characterization takes the form

\[
\inf_{\mu \in \mathbb{C}} \sup_\gamma \sigma_{2n-1} \left( \begin{bmatrix} A - \mu B & 0 \\ \gamma B & A - \mu B \end{bmatrix} \right). \tag{8.1}
\]

Specifically, we consider the pencil

\[
A - \lambda B = \begin{bmatrix} 2 & -1 & -1 \\ -1 & 2 & -1 \\ -1 & -1 & 2 \end{bmatrix} - \lambda \begin{bmatrix} -1 & 2 & 3 \\ 2 & -1 & 2 \\ 4 & 2 & -1 \end{bmatrix}. \tag{8.2}
\]

Solving the above singular value optimization problem results in a distance of 0.59299 to the nearest pencil with a multiple eigenvalue. By (4.4), a nearest pencil turns out to be

\[
\begin{bmatrix} 1.91465 & -0.57896 & -1.21173 \\ -1.32160 & 1.93256 & -0.57897 \\ -0.72082 & -1.32160 & 1.91466 \end{bmatrix} - \lambda \begin{bmatrix} -1 & 2 & 3 \\ 2 & -1 & 2 \\ 4 & 2 & -1 \end{bmatrix},
\]

with the double eigenvalue \( \lambda_\ast = -0.85488 \). The optimal maximizing \( \gamma \) turns out to be zero, which means neither the multiplicity nor the linear independence qualifications hold. (This is the nongeneric case; had we attempted to calculate the distance to the nearest pencil with \( \mu \) as a multiple eigenvalue
for a given $\mu$, optimal $\gamma$ appears to be nonzero for generic values of $\mu$.) Nevertheless, the singular value characterization (8.1) remains true for the distance as discussed next.

The $\epsilon$-pseudospectrum of $A - \lambda B$ (subject to perturbations in $A$ only) is the set $\Lambda_\epsilon(A,B)$ containing the eigenvalues of all pencils $(A + \Delta A) - \lambda B$ such that $\|\Delta A\|_2 \leq \epsilon$. Equivalently,

$$\Lambda_\epsilon(A,B) = \{ \lambda \in \mathbb{C} : \sigma_{\min}(A - \lambda B) \leq \epsilon \}.$$

It is well known that the smallest $\epsilon$ such that two components of $\Lambda_\epsilon(A,B)$ coalesce equals the distance to the nearest pencil with multiple eigenvalues. (See Alam & Bora, 2005 for the case $B = I$, but the result easily extends to arbitrary invertible $B$.) Figure 1 displays the pseudospectra of the pencil in (8.2) for various levels of $\epsilon$. Indeed, two components of the $\epsilon$-pseudospectrum coalesce for $\epsilon = 0.59299$, confirming our result.

8.2 Nearest rectangular pencils with at least two eigenvalues

As an example for a rectangular pencil, let us consider the $4 \times 3$ pencil

$$A - \lambda B = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 0.1 & 0 \\ 0 & 2 & 0.3 \\ 0 & 1 & 2 \end{bmatrix} - \lambda \begin{bmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}.$$
The KCF of this pencil contains a $4 \times 3$ singular block and therefore the pencil has no eigenvalues. However, if the entry $a_{22}$ is set to zero, then the KCF of the resulting pencil contains a $2 \times 1$ singular block and a $2 \times 2$ regular block corresponding to finite eigenvalues. Hence, a perturbation with 2-norm 0.1 is sufficient to have two eigenvalues.

According to the corollaries in Section 5 the distance to the nearest $4 \times 3$ pencil with at least two eigenvalues has the characterization

$$\tau_2(\mathbb{C}) = \inf_{\mu \in \mathbb{C}^2} \sup_{\gamma} \sigma_{2m-1} \left( \begin{bmatrix} A - \mu_1 B & 0 \\ \gamma B & A - \mu_2 B \end{bmatrix} \right)$$

for $m = 3$. Our implementation returns $\tau_2(\mathbb{C}) = 0.03927$. The corresponding nearest pencil (4.4) is given by

$$\begin{bmatrix} 0.99847 & -0.03697 & -0.01283 \\ 0 & 0.08698 & 0.03689 \\ 0 & 2.00172 & 0.30078 \\ 0.00007 & 1.00095 & 2.00376 \end{bmatrix} - \lambda \begin{bmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

and has eigenvalues at $\mu_1 = 2.55144$ and $\mu_2 = 1.45405$. This result is confirmed by Fig. 2, which illustrates the level sets of the function $g(\mu)$ defined in (8.3) over $\mathbb{R}^2$.

For this example the optimal $\gamma$ is 2.0086. The smallest three singular values of the matrix in (8.3) are 1.4832, 0.0393 and 0.0062 for these optimal values of $\mu$ and $\gamma$. The linear independence qualification also holds.
Fig. 3. Pseudospectra of the matrix $A$ defined in (8.4). The outer orange curve represents the boundary of the $\epsilon$-pseudospectrum for $\epsilon = 0.6610$, the distance to a nearest stable matrix.

8.3 Nearest stable pencils

As a final example, suppose that $Bx'(t) = Ax(t)$, with $A, B \in \mathbb{C}^{n \times n}$, is an unstable descriptor system. The distance to a nearest stable descriptor system is a special case of $\tau_n(\Omega)$, with $\Omega = \mathbb{C}^-$, the open left half of the complex plane. A singular value characterization is given by

$$\tau_n(\mathbb{C}^-) = \inf_{\lambda_j \in \mathbb{C}^-} \sup_{\gamma_{ik} \in \mathbb{C}} \sigma_{n^2-n+1} \begin{pmatrix} A - \lambda_1 B & 0 & 0 \\ \gamma_{21} B & A - \lambda_2 B & 0 \\ \vdots & \ddots & \vdots \\ \gamma_{n1} B & \gamma_{n2} B & A - \lambda_n B \end{pmatrix}.$$ 

Specifically, we consider a system with $B = I_2$ and

$$A = \begin{bmatrix} 0.6 - \frac{1}{3}i & -0.2 + \frac{4}{3}i \\ -0.1 + \frac{2}{3}i & 0.5 + \frac{1}{3}i \end{bmatrix}.$$ 

Both eigenvalues $\lambda_1 = 0.7 - i$ and $\lambda_2 = 0.4 + i$ are in the right-half plane. Based on the singular value characterization, we have computed the distance to a nearest stable system $x'(t) = (A + \Delta A_e)x(t)$ as 0.6610. The corresponding perturbed matrix

$$A + \Delta A_e = \begin{bmatrix} 0.0681 - 0.3064i & -0.4629 + 1.2524i \\ 0.2047 + 0.5858i & -0.1573 + 0.3064i \end{bmatrix}.$$
at a distance of 0.6610 has one eigenvalue \((\lambda_1) = -0.0885 + 0.9547i\) in the left-half plane and the other, \((\lambda_2) = -0.9547i\), on the imaginary axis. The \(\epsilon\)-pseudospectrum of \(A\) is depicted in Fig. 3. For \(\epsilon = 0.6610\), one component of the \(\epsilon\)-pseudospectrum crosses the imaginary axis, while the other component touches the imaginary axis.

9. Concluding remarks

In this work a singular value characterization has been derived for the 2-norm of a smallest perturbation to a square or a rectangular pencil \(A - \lambda B\) such that the perturbed pencil has a desired set of eigenvalues. The immediate corollaries of this main result are

(i) a singular value characterization for the 2-norm of the smallest perturbation so that the perturbed pencil has a specified number of its eigenvalues in a desired region in the complex plane, and

(ii) a singular value characterization for the 2-norm of the smallest perturbation to a rectangular pencil so that it has a specified number of eigenvalues.

Partly motivated by an application explained in the introduction, we allow perturbations to \(A\) only. The extension of our results to the case of simultaneously perturbed \(A\) and \(B\) remains open.

The development of efficient and reliable computational techniques for the solution of the derived singular value optimization problems is still in progress. As of now the optimization problems can be solved numerically only for small pencils with a small number of desired eigenvalues. The main task that needs to be addressed from a computational point of view is a reliable and efficient implementation of the DIRECT algorithm for Lipschitz-based optimization. For prescribing more than a few eigenvalues it is necessary to develop Lipschitz-based algorithms converging asymptotically faster than the algorithms (such as the DIRECT algorithm) stemming from the Piyavskii–Shubert algorithm. The derivatives from Section 4.1 might constitute a first step in this direction.

GENERALIZED EIGENVALUE PROBLEMS WITH SPECIFIED EIGENVALUES 499

Appendix. Proof that $\sigma_{mr-r+1}(\mathcal{L}(\mu, \Gamma, A, B)) \to 0$ as $\Gamma \to \infty$

We prove that the $r$ smallest singular values of $\mathcal{L}(\mu, \Gamma, A, B)$ decay to zero as soon as at least one entry of $\Gamma$ tends to infinity, provided that $n = m$. In the rectangular case, $n > m$, these singular values generally do not decay to zero.

We start by additionally assuming that $A - \mu_i B$ are nonsingular matrices for all $i = 1, \ldots, r$. We will first prove the result under this assumption, and then we will drop it. Our approach is a generalization of the procedure from Ikramov & Nazari (2005, Section 5), which in turn is a generalization of Malyshev (1999, Lemma 2).

Under our assumptions the matrix $\mathcal{L}(\mu, \Gamma, A, B)$ is nonsingular, and one can explicitly calculate the inverse. It is easy to see that the matrix $\mathcal{L}^{-1}(\mu, \Gamma, A, B)$ has the form

$$
\begin{bmatrix}
(A - \mu_1 B)^{-1} & 0 & \cdots & 0 \\
X_{21} & (A - \mu_2 B)^{-1} & \cdots & 0 \\
X_{31} & X_{32} & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
X_{r1} & X_{r2} & \cdots & (A - \mu_r B)^{-1}
\end{bmatrix}.
$$

We will use the well-known relations

$$
\sigma_{mr-r+1}(\mathcal{L}(\mu, \Gamma, A, B)) = \sigma_r(\mathcal{L}(\mu, \Gamma, A, B)^{-1})^{-1} \leq \sigma_r(X_1)^{-1}. \quad (A.1)
$$

We first compute the matrices $X_{21}, \ldots, X_{r,r-1}$ which lie on the first subdiagonal. By a straightforward computation, we obtain

$$
X_{i+1,i} = -\gamma_{i+1,i}(A - \mu_{i+1} B)^{-1} B (A - \mu_i B)^{-1}.
$$

If $\sigma_r((A - \mu_{i+1} B)^{-1} B (A - \mu_i B)^{-1}) > 0$, then from (A.1) it follows that if any of $|\gamma_{i+1,i}|$ tend to infinity, we obtain the desired result. But $\sigma_r((A - \mu_{i+1} B)^{-1} B (A - \mu_i B)^{-1}) > 0$ easily follows from the assumption rank$(B) \geq r$.

If this is not the case, meaning max$_i |\gamma_{i+1,i}|$ is bounded, then we use the entries on the next subdiagonal $X_{i+2,i}$. Again by straightforward computation, we obtain

$$
X_{i+2,i} = -\gamma_{i+2,i}(A - \mu_{i+2} B)^{-1} B (A - \mu_i B)^{-1}
$$

$$
+ \gamma_{i+2,i+1} \gamma_{i+1,i}(A - \mu_{i+2} B)^{-1} B (A - \mu_{i+1} B)^{-1} B (A - \mu_i B)^{-1}.
$$

Again because rank$(B) \geq r$ implies $\sigma_r((A - \mu_{i+2} B)^{-1} B (A - \mu_i B)^{-1}) > 0$, it follows that if any of $|\gamma_{i+2,i}|$ tend to infinity, we obtain the desired result. In general, we have the recursive formula

$$
X_{i+j,i} = -\gamma_{i+j,i}(A - \mu_{i+j} B)^{-1} B (A - \mu_i B)^{-1} - \sum_{k=1}^{j-1} \gamma_{i+j,i+k} (A - \mu_{i+j} B)^{-1} B X_{i+k,i}.
$$

Applying the same procedure as above, we conclude the proof in this case.
To remove the assumption that the matrices \( A - \mu_i B \) are nonsingular, we fix any \( \varepsilon > 0 \). Let us choose a matrix \( A_\varepsilon \) such that \( \| A_\varepsilon - A \| < \varepsilon \) and such that the matrices \( A_\varepsilon - \mu_i B \) are nonsingular for all \( i = 1, \ldots, r \). From the arguments above, it follows that there exists \( \gamma_0 > 0 \) such that 
\[
\sigma_{nr-r+1}(L(\mu, \Gamma, A_\varepsilon, B)) < \varepsilon \quad \text{when} \quad \| \Gamma \| > \gamma_0.
\]
Since
\[
\sigma_{nr-r+1}(L(\mu, \Gamma, A, B)) \leq \sigma_{nr-r+1}(L(\mu, \Gamma, A_\varepsilon, B)) + \varepsilon,
\]
we obtain the inequality \( \sigma_{nr-r+1}(L(\mu, \Gamma, A, B)) < 2\varepsilon \) when \( \| \Gamma \| > \gamma_0 \).
