Combinatorial Penalties:
Which structures are preserved by convex relaxations?

Abstract

We consider the homogeneous and the non-homogeneous convex relaxations for combinatorial penalty functions defined on support sets. Our study identifies key differences in the tightness of the resulting relaxations through the notion of the lower combinatorial envelope of a set-function along with new necessary conditions for support identification. We then propose a general adaptive estimator for convex monotone regularizers, and derive new sufficient conditions for support recovery in the asymptotic setting.

1 Introduction

Over the last years, sparsity has been a key model in machine learning, signal processing, and statistics. While sparsity modelling is powerful, structured sparsity models further exploit domain knowledge by characterizing the interdependency between the non-zero coefficients of an unknown parameter vector $w$. For example, in certain applications domain knowledge may dictate that we should favor non-zero patterns corresponding to: unions of groups in cancer prognosis from gene expression data; or complements of union of groups in neuroimaging and background subtraction, or rooted connected trees in natural image processing. Incorporating such key prior information beyond just sparsity leads to significant improvements in estimation performance, noise robustness, interpretability and sample complexity.

Structured sparsity models are naturally encoded by combinatorial functions. However, direct combinatorial treatments often lead to intractable learning problems. Hence, we often use either non-convex greedy methods or continuous convex relaxations, where the combinatorial penalty is replaced by a tractable convex surrogate; cf., [4][20][2].

In this paper, we adopt the convex approach because it benefits from a mature set of efficient numerical algorithms as well as strong analysis tools that rely on convex geometry in order to establish statistical efficiency. Convex formulations are also robust to model mis-specifications. Moreover, there is a rich set of convex penalties with structure-inducing properties already studied in the literature [26][21][20][22][37][32]. For an overview, we refer the reader to [2] and references therein.

For choosing a convex relaxation, a systematic approach, already adopted in [1][6][31][10], considers the tightest convex relaxation of combinatorial penalties expressing the desired structure. For instance, [1] shows that computing the tightest convex relaxation over the unit $\ell_\infty$-ball is tractable for the ensemble of monotone submodular functions. Similarly, the authors in [10] demonstrates the tractability of such relaxation for combinatorial penalties that can be described via totally unimodular constraints.

A different principled approach in convex relaxations is proposed by [31], where the authors considered the tightest homogeneous convex relaxation of general set functions regularized by an $\ell_p$-norm. The authors show, for instance, the resulting norm takes the form of a generalized latent group Lasso norm [32]. The homogeneity imposed in [31] naturally ensures the invariance of the regularizer to rescaling of the data. However, such requirement may cost a loss of structure as was observed in an example in [10]. This observation begs the question:

When do the homogeneous and non-homogeneous convex relaxations differ and which structures can be encoded by each?

In order to answer this question, we rigorously identify which combinatorial structures are preserved by the non-homogeneous relaxation in a manner similar to [31] for the homogeneous one. We further study the statistical properties of both relaxations. In particular, we consider the problem of support recovery in the context of regularized learning problems by these relaxed convex penalties, which was only investigated so far in special cases, e.g., for norms associated with submodular functions [1], or for the latent group Lasso norm [32].
To this end, this paper makes the following contributions:

- We derive formulations of the non-homogeneous tightest convex relaxation of general $\ell_p$-regularized combinatorial penalties (Section 2.1). We show that any monotone set function is preserved by such relaxation, while the homogeneous relaxation only preserves a smaller subset of set-functions (Section 2.2).
- We identify necessary conditions for support recovery in learning problems regularized by general convex penalties (Section 3.1).
- We propose an adaptive weight estimation scheme and provide sufficient conditions for support recovery under the asymptotic regime (Section 3.2). This scheme does not require any irrepresentability condition and is applicable to general monotone convex regularizers.
- We identify sufficient conditions with respect to combinatorial penalties which ensure that the sufficient support recovery conditions hold with respect to the associated convex relaxations (Section 4).
- We illustrate numerically the effect on support recovery of the choice of the relaxation as well as the adaptive weights scheme (Section 5).

In the sequel, we defer all proofs to the Appendix.

**Notation.** Let $V = \{1, \ldots, d\}$ be the ground set and $2^V = \{A|A \subseteq V\}$ be its power-set. Given $w \in \mathbb{R}^d$ and a set $J \subseteq V$, $w_{\lfloor J\rceil}$ denotes the vector in $\mathbb{R}^d$ s.t., $[w_{\lfloor J\rceil}]_i = w_i, i \in J$ and $[w_{\lfloor J\rceil}]_i = 0, i \notin J$. $Q_{J,J'}$ is defined similarly for a matrix $Q \in \mathbb{R}^{d \times d}$. Accordingly, we let $I_{\lfloor J\rceil}$ be the indicator vector of the set $J$. We drop the subscript for $J = V$, so that $I_V = 1$ denotes the vector of all ones. The notation $J^c$ denotes the set complement of $J$ with respect to $V$.

The operations $|w|, w \geq w'$ and $w \circ v$ are applied element-wise. For $p > 0$, the $\ell_p$-(quasi) norm is given by $\|w\|_p = (\sum_{i=1}^{d} |w_i|^p)^{1/p}$, and $\|w\|_\infty = \max_i |w_i|$. For $p \in [1, \infty)$, we define the conjugate $q \in [1, \infty]$ via $\frac{1}{p} + \frac{1}{q} = 1$.

We call the set of non-zero elements of a vector $w$ the support, denoted by $\text{supp}(w) = \{i : w_i \neq 0\}$. We use the notation from submodular analysis, $w(A) = \sum_{i \in A} w_i$. We write $\mathbb{R}_{+}$ for $\mathbb{R} \cup \{+\infty\}$. For a function $f : \mathbb{R}^d \rightarrow \mathbb{R} = \mathbb{R} \cup \{+\infty\}$, we will denote by $f^*$ its Fenchel-Legendre conjugate. We will denote by $\ell_S(w)$ the indicator function of the set $S$, taking value 0 on the set $S$ and $+\infty$ outside it.

## 2 Combinatorial penalties and convex relaxations

We consider positive-valued set functions of the form $F : 2^V \rightarrow \mathbb{R}_{+}$ such that $F(\emptyset) = 0, F(A) > 0, \forall A \subseteq V$ to encode structured sparsity models. For generality, we do not assume a priori that $F$ is monotone (i.e., $F(A) \leq F(B), \forall A \subseteq B$). However, as we argue in the sequel, convex relaxations of non-monotone set functions is hopeless.

The domain of $F$ is defined as $\mathcal{D} := \{A : F(A) \leq +\infty\}$. We assume that it covers $V$, i.e., $\cup_{A \in \mathcal{D}} A = V$, which is equivalent to assuming that $F$ is finite at singletons if $F$ is monotone. A finite-valued set function $F$ is submodular if and only if for all $A \subseteq B$ and $i \in B^c$, $F(B \cup \{i\}) - F(B) \leq F(A \cup \{i\}) - F(A)$ (see, e.g., [15, 2]). Unless explicitly stated, we do not assume that $F$ is submodular.

We consider the same model in [31], parametrized by $w \in \mathbb{R}^d$, with general $\ell_p$-regularized combinatorial penalties:

$$F_p(w) = \frac{1}{q} F(\text{supp}(w)) + \frac{1}{p} \|w\|_p^p$$

for $p \geq 1$, where the set function $F$ controls the structure of the model in terms of allowed/favored non-zero patterns and the $\ell_p$-norm serves to control the magnitude of the coefficients. Allowing $F$ to take infinite values lets us enforce hard constraints. For $p = \infty$, $F_p$ reduces to $F_\infty(w) = F(\text{supp}(w)) + \|w\|_\infty \leq (\eta)$. Considering the case $p \neq \infty$ is appealing to avoid the clustering artifacts of the values of the learned vector induced by the $\ell_\infty$-norm.

Since such combinatorial regularizers lead to computationally intractable problems, we seek convex surrogate penalties that capture the encoded structure as much as possible. A natural candidate for a convex surrogate of $F_p$ is then its convex envelope (largest convex lower bound), given by the biconjugate (the Fenchel conjugate of the Fenchel conjugate) $F_p^\times$. Two general approaches are proposed in the literature to achieve just this; one requires the surrogate to also be positively homogeneous [31] and thus considers the convex envelope of the positively homogeneous envelope of $F_p$, given by $F(\text{supp}(w))^{\frac{1}{q}}\|w\|_p\alpha$, which we denote by $\Omega_p$, the other computes instead the convex envelope of $F_p$ directly [10, 11], which we denote by $\Theta_p$. Note that from the definition of convex envelope, it holds that $\Theta_p \geq \Omega_p$.

### 2.1 Homogeneous and non-homogeneous convex envelopes

In [31], the homogeneous convex envelope $\Omega_p$ of $F_p$ was shown to correspond to the latent group Lasso norm [32] with groups set to all elements of the power set $2^V$. We recall this form of $\Omega_\infty$ in Lemma 1 as well as a variational form of $\Omega_p$ which highlights the relation between the two.

Other variational forms can be found in the Appendix.

**Lemma 1 ([31]).** The homogeneous convex envelope $\Omega_p$ of $F_p$ is given by

$$\Omega_p(w) = \inf_{\eta \in \mathbb{R}_{+}} \left\{ \frac{1}{q} \sum_{j=1}^{d} \frac{|w_j|^p}{\eta_j^p} + \frac{1}{q} \Omega_\infty(\eta) \right\}, \tag{1}$$

$$\Omega_\infty(w) = \min_{\alpha \geq 0} \left\{ \sum_{S \subseteq V} \alpha_S F(S) : \sum_{S \subseteq V} \alpha_S \ell_S \geq |w| \right\}. \tag{2}$$
The non-homogeneous convex envelope \( \Theta_p \) of \( F_p \) is only considered thus far in the case where \( p = \infty \). \(^{[10]} \) shows that \( \Theta_{\infty}(w) = \inf_{\eta \in [0,1]^d} \{ f(\eta) : \eta \geq |w| \} \) where \( f \) is any proper (dom(\( f \)) \( \neq \emptyset \)) lower semi-continuous (l.s.c.) convex extension of \( F \), i.e., \( f(1_A) = F(A), \forall A \subseteq V \) (cf., Lemma 1 in \(^{[10]} \)). A natural choice for \( f \) is the convex closure of \( F \), which corresponds to the tightest convex extension of \( F \) on \([0,1]^d \) (cf., Appendix for a more rigorous treatment).

Lemma 2 below presents this choice, deriving a new form of \( \Theta_{\infty} \) that parallels \(^{[4]} \). We also derive the non-homogeneous convex envelope \( \Theta_p \) of \( F_p \) for any \( p \geq 1 \) and present the variational form relating it to \( \Theta_{\infty} \) in Lemma 2. For simplicity, the variational form \(^{[3]} \) presented below holds only for monotone functions \( F \); the general form and other variational forms that parallel the ones known for the homogeneous envelope are presented in the Appendix.

**Lemma 2.** The non-homogeneous convex envelope \( \Theta_p \) of \( F_p \), for monotone functions \( F \), is given by

\[
\Theta_p(w) = \inf_{\eta \in [0,1]^d} \left\{ \frac{1}{p} \sum_{i=1}^{d} |w_i|^p + \frac{1}{q} \Theta_{\infty}(\eta) \right\},
\]

\[
\Theta_{\infty}(w) = \min_{\alpha \geq 0} \left\{ \sum_{S \subseteq V} \alpha_S \{ F(S) : \sum_{S \subseteq V} \alpha_S 1_S \geq |w|, \sum_{S \subseteq V} \alpha_S = 1 \} \right\}.
\]

The infima in \(^{[1]} \) and \(^{[3]} \), for \( w \in \text{dom}(\Theta_p) \), can be replaced by a minimization, if we extend \( b \to \frac{b}{a} \) by continuity in zero with \( \frac{\infty}{0} = \infty \) if \( a \neq 0 \) and \( 0 \) otherwise, as suggested in \(^{[24]} \) and \(^{[3]} \). Note that, for \( p = 1 \), both relaxations reduce to \( \Omega_1 = \Theta_1 = \| \cdot \|_1 \). Hence, the \( \ell_1 \)-relaxations essentially lose the combinatorial structure encoded in \( F \). We thus follow up on the case \( p > 1 \).

In order to decide when to employ \( \Omega_p \) or \( \Theta_p \), it is of interest to study the respective properties of these two relaxations and to identify when they coincide. Remark \(^{[1]} \) shows that the homogeneous and non-homogeneous envelopes are identical, for \( p = \infty \), for monotone submodular functions.

**Remark 1.** If \( F \) is a monotone submodular function then \( \Theta_{\infty}(w) = \Omega_{\infty}(w) = f_L(|w|), \forall w \in [-1,1]^d \), where \( f_L \) denotes the Lovász extension of \( F \). \(^{[28]} \)

The two relaxations do not coincide in general: Note the added constraints \( \eta \in [0,1]^d \) in \(^{[5]} \) and the sum constraint on \( \alpha \) in \(^{[4]} \). Another clear difference to note is that \( \Omega_p \) are norms that belong to the broad family of H-norms \(^{[29]} \), \(^{[3]} \), as shown in \(^{[31]} \). On the other hand, by virtue of being non-homogeneous, \( \Theta_p \) are not norms in general. We illustrate below two interesting examples where \( \Omega_p \) and \( \Theta_p \) differ.

**Example 1** (Berhu penalty). Since the cardinality function \( F(S) = |S| \) is a monotone submodular function, \( \Theta_{\infty}(w) = \Omega_{\infty}(w) = \|w\|_1 \). However, this is not the case for \( p \neq \infty \). In particular, we consider the \( \ell_2 \)-regularized cardinality function \( F^\text{card}_2(w) = \frac{1}{2} \|w\|_0 + \frac{1}{2} \|w\|_2^2 \). Figure \(^{[27]} \) shows that the non-homogeneous envelope is tighter than the homogeneous one in this case. Indeed, \( \Omega_{\text{card}}^2 \) is simply the \( \ell_1 \)-norm, while \( \Theta_{\text{card}}^2 \) is given by \( \Theta_{\text{card}}^2(w) = |w| \) if \( |w| \leq 1 \) and \( \Theta_{\text{card}}^2(w) = \frac{1}{2} |w|^2 + \frac{1}{2} \) otherwise. This penalty, called “Berhu,” is introduced in \(^{[23]} \) to produce a robust ridge regression estimator and is shown to be the convex envelope of \( F^\text{card}_2 \) in \(^{[22]} \).

This kind of behavior, where the non-homogeneous relaxation \( \Theta_p \) acts as an \( \ell_1 \)-norm on the small coefficients and as \( \frac{1}{p} \|w\|_p \) for large ones, is not limited to the Berhu penalty, but holds for general set functions. However the point where the penalty moves from one mode to the other depends on the structure of \( F \) and is different along each coordinate. This is easier to see via the second variational form of \( \Theta_p \) presented in the Appendix. We further illustrate in the following example.

**Example 2** (Range penalty). Consider the range function defined as \( \text{range}(A) = \max(A) - \min(A) + 1 \) where \( \max(A) (\min(A)) \) denotes maximal (minimal) element in \( A \). This penalty allows us to favor the selection of interval non-zero patterns on a chain or rectangular patterns on grids. It was shown in \(^{[37]} \) that \( \Omega_p(w) = \|w\|_1 \) for any \( p \geq 1 \). On the other hand, \( \Theta_p \) has no closed form solution, but is different from \( \ell_1 \)-norm. Figure \(^{[27]} \) illustrates the balls of different radii of \( \Theta_{\infty} \) and \( \Theta_2 \). We can see how the penalty morphs from \( \ell_1 \)-norm to \( \ell_2 \) and squared \( \ell_2 \)-norm respectively, with different “speed” along each coordinate. Looking carefully for example on the ball \( \Theta_2(w) \leq 2 \), we can see that the penalty acts as an \( \ell_1 \)-norm along the \((x,z)\)-plane and as a squared \( \ell_2 \)-norm along the \((y,z)\)-plane.

We highlight other ways in which the two relaxations differ and their implications in the sequel.

In terms of computational efficiency, note that even though the formulations \(^{[1]} \) and \(^{[4]} \) are jointly convex in \((w, \eta)\), \( \Omega_p \) and \( \Theta_p \) can still be intractable to compute and to optimize. However, for certain classes of functions, they are tractable. For example, since for monotone submodular functions, \( \Omega_{\infty} = \Theta_{\infty} \) is the Lovász extension of \( F \), as stated in Remark \(^{[1]} \) then they can be efficiently computed by the greedy algorithm \(^{[2]} \). Moreover, efficient algorithms to compute \( \Omega_p \), the associated proximal operator and to solve learning problems regularized with \( \Omega_p \) is proposed in \(^{[31]} \). Similarly, if \( F \) can be expressed by integer programs over totally unimodular constraints as in \(^{[10]} \), then \( \Omega_{\infty} = \Theta_{\infty} \) and their associated Fenchel-type operators can be computed efficiently by linear programs. Hence, we can use conditional gradient algorithms for numerical solutions.

### 2.2 Lower combinatorial envelopes

In this section, we are interested in analyzing which combinatorial structures are preserved by each relaxation. To
that end, we generalize the notion of lower combinatorial envelope (LCE) \([31]\). The homogeneous LCE \(F^-\) of \(F\) is defined as the set function which agrees with the \(\ell_\infty\)-homogeneous convex relaxation of \(F\) at the vertices of the unit hypercube, i.e., \(F^-(A) = \Omega_\infty(1_A), \forall A \subseteq V\).

For the non-homogeneous relaxation, we define the non-homogeneous LCE similarly as \(F^-(A) = \Theta_\infty(1_A)\). The \(\ell_\infty\)-relaxation reflects most directly the combinatorial structure of the function \(F\). Indeed, \(\ell_p\)-relaxations only depend on \(F\) through the \(\ell_\infty\)-relaxation as expressed in the variational forms \([1]\) and \([3]\).

We say \(\Omega_\infty\) is a tight relaxation of \(F\) if \(F = F^-\). Similarly, \(\Theta_\infty\) is a tight relaxation of \(F\) if \(\tilde{F}^- = F, \Omega_\infty\) and \(\Theta_\infty\) are then extensions of \(F\) from \([0, 1]^d\) to \(\mathbb{R}^d\); in this sense, the relaxation is tight for all \(w\) of the form \(w = 1_A\). Moreover, following the definition of convex envelope, the relaxation \(\Omega_\infty\) (resp. \(\Theta_\infty\)) is the same for \(F\) and \(\tilde{F}^-\) (resp. \(F\) and \(\tilde{F}^-\)), and hence, the LCE can be interpreted as the combinatorial structure preserved by each convex relaxation.

The homogeneous relaxation can capture any monotone submodular function \([31]\). Since \(\Omega_\infty\) is the Lovász extension \([1]\) in this case, and hence, \(F^-(A) = \Omega_\infty(1_A) = f_L(1_A) = F(A)\). Also, since the two \(\ell_\infty\)-relaxations are identical for this class of functions, their LCEs are also equal, i.e., \(\tilde{F}^-(A) = \Theta_\infty(1_A) = \Omega_\infty(1_A) = F(A)\).

The LCEs, however, are not equal in general. In fact, the non-homogeneous relaxation is tight for a larger class of functions. In particular, the following proposition shows that \(\tilde{F}^-\) is equal to the monotonomization of \(F\), that is \(\tilde{F}^-(A) = \inf_{S \subseteq V} \{F(S) : A \subseteq S\}\), for all set functions \(F\), and is thus equal to the function itself if \(F\) is monotone.

**Proposition 1.** The non-homogenous lower combinatorial envelope can be written as

\[
\tilde{F}^-(A) = \Theta_\infty(1_A) = \left\{ \sum_{S \subseteq V} \alpha_S F(S) : \sum_{S \subseteq V} \alpha_S 1_A, \sum_{S \subseteq V} \alpha_S = 1 \right\}
\]

**Proof.** To see why we can restrict \(\alpha_S\) to be integral, let \(E = \{S : \alpha_S > 0\}\), then \(\forall S \subseteq V\) such that \(\exists e \in A, e \notin T\), then \(\sum_{S \supseteq T} \alpha_S = 1\) and hence \(\alpha_T = 0\). Hence \(\forall S \in E\), we have \(A \subseteq S\) and \(\sum_{S \subseteq V} \alpha_S F(S) = \min_{S \supseteq A} F(S)\).

Proposition 1 argues that the non-homogenous convex envelope is tight if and only if \(F\) is monotone. Two important practical implications follow from this result.

Given a target model that cannot be expressed by a monotone function, it is impossible to obtain a tight convex relaxation. Non-convex methods can be potentially better.

On the other hand, if the model can be expressed by a monotone non-submodular set function, the homogeneous function may not be tight, and hence, a non-homogeneous relaxation can be more useful. For instance, \([31]\) shows that for any set function where \(F([e]) = 1\) for all singletons \(e \in V\) and \(F(A) \geq |A|, \forall A \subseteq V\), the homogeneous LCE \(F^-(A) = |A|\) and accordingly \(\Omega_\infty\) is the \(\ell_1\)-norm, thus losing completely the structure encoded in \(F\).

We discuss three examples that fall in this class of functions, where the non-homogeneous relaxation is tight while the homogeneous one is not.

**Example 3** (Range penalty). Consider range\((A) = \max(A) - \min(A) + 1\). For \(F(A) = \text{range}(A)\), we have \(F^-(A) = |A|\), while \(\tilde{F}^- = F\) by Prop. 4.

**Example 4** (Dispersive \(\ell_0\)-penalty). Given a set of predefined groups \(\{G_1, \ldots, G_M\}\), consider the dispersive \(\ell_0\)-

![Figure 1: \(\ell_2\)-regularized cardinality example in one dimension (left) and two dimensions (middle: homogeneous, right: non-homogeneous).](image1)

![Figure 2: Balls of different radii of the non-homogeneous \(\ell_\infty\)-convex envelope of the range function (top): \(\Theta_\infty(w) \leq 1\) (left), \(\Theta_\infty(w) \leq 2\) (middle), \(\Theta_\infty(w) \leq 3\) (right) and of its \(\ell_2\)-convex envelope (bottom): \(\Theta_2(w) \leq 1\) (left), \(\Theta_2(w) \leq 2\) (middle), \(\Theta_2(w) \leq 4\) (right).](image2)
penalty, introduced by [10]: $F(A) = |A| + \lambda_\infty \mathbf{1}_{\|A\|_\infty \leq 1}(A)$ where the columns of $B$ correspond to the indicator vectors of the groups, i.e., $B_{V_i} = \mathbf{1}_{G_i}$. The dispersive penalty enforces the selection of sparse supports where no two non-zeros are selected from the same group. Neural sparsity models induce such structures [18]. In this case, we have $F_-(A) = |A|$, while $F_- = F$ by Prop. [4]

**Example 5** (Weighted graph model). Given a graph $G = (V, E)$, consider a relaxed version of the weighted graph model of [19]: $F(A) = |A| + \gamma(F_A) \leq \omega(F_A) \leq B(A)$, where $\gamma(F_A)$ is the number of connected components formed by the forest $F_A$ corresponding to $A$ and $\omega(F_A)$ is the total weight of edges in the forest $F_A$. This model describes a wide range of structures, including 1D-clustering, tree hierarchies, and the Earth Mover Distance model. We have $F_-(A) = |A|$, while $F_- = F$ by Prop. [4].

The last two examples belong to a natural class of structured sparsity penalties of the form $F(A) = |A| + \lambda_\infty \mathbf{1}_{\|A\|_\infty \leq 1}(A)$, which favors sparse non-zero patterns among a set $M$ of allowed patterns. If $M$ is down-monotone, i.e., $\forall A \in M, \forall B \subseteq A, B \in M$, then the non-homogeneous relaxation preserves its structure, i.e., $\hat{F}_- = F$, while its homogeneous relaxation is oblivious to the hard constraints, with $F_-(A) = |A|$.

### 3. Sparsity-inducing properties of convex relaxations

The notion of LCE captures the combinatorial structure preserved by convex relaxations in a geometric sense. In this section, we characterize the preserved structure from a statistical perspective.

To this end, we consider the linear regression model $y = Xw^* + \epsilon$, where $X \in \mathbb{R}^{n \times d}$ is a fixed design matrix, $y \in \mathbb{R}^n$ is the response vector, and $\epsilon$ is a vector of iid random variables with mean 0 and variance $\sigma^2$. Given $\lambda_n > 0$, we define $\hat{w}$ as a minimizer of the regularized least-squares:

$$\min_{w \in \mathbb{R}^d} \frac{1}{2} \|y - Xw\|_2^2 + \lambda_n \Phi(w), \quad (5)$$

We are interested in the sparsity-inducing properties of $\Omega_p$ and $\Theta_p$ on the solutions of (5). In this section, we consider though the more general setting where $\Phi$ is any proper normalized ($\Phi(0) = 0$) convex function which is absolute, i.e., $\Phi(w) = \Phi(|w|)$ and monotonic in the absolute values of $w$, that is $|w| \geq |w'| \Rightarrow \Phi(w) \geq \Phi(w')$. In what follows, monotone functions refer to this notion of monotonicity.

We determine in Section 3.4 necessary conditions for support recovery in (5) and in Section 3.5 we provide sufficient conditions for support recovery and consistency of a variant of (5). As both $\Omega_p$ and $\Theta_p$ are normalized absolute monotone convex functions, the results presented in this section apply directly to them as a corollary.

For simplicity, we assume $Q = X^T X/n \succ 0$, thus $\hat{w}$ is unique. This forbids the high-dimensional setting. We expect though the insights developed towards the presented results to contribute to understanding the high-dimensional learning setting, which we defer to a later work.

### 3.1 Continuous stable supports

Existing results on the consistency of special cases of the estimator (5) typically rely heavily on decomposition properties of $\Phi$ [30, 1, 32, 31]. The notions of decomposability assumed in these prior works are either too strong or too specific to be applicable to the general convex penalties $\Omega_p$ and $\Theta_p$ we are considering. Instead, we introduce a general weak notion of decomposability applicable to any absolute monotone convex regularizer.

**Definition 1** (Decomposability). Given $J \subseteq V$ and $w \in \mathbb{R}^d$, supp($w$) $\subseteq J$, we say that $\Phi$ is decomposable at $w$ w.r.t. $J$ if $\exists M_J > 0$ such that $\forall \Delta \in \mathbb{R}^d$, supp($\Delta$) $\subseteq J^c$, $\Phi(w + \Delta) \geq \Phi(w) + M_J \|\Delta\|_\infty$.

For example, for the $\ell_1$-norm, this decomposability property holds for any $J \subseteq V$ and $w \in \mathbb{R}^d$, with $M_J = 1$.

It is reasonable to expect this property to hold at the solution $\hat{w}$ of (5) and its support $J = \text{supp}(\hat{w})$. Theorem [1] shows that this is indeed the case. In Section 3.2, we devise an estimation scheme able to recover supports $J$ that satisfy this property at any $w \in \mathbb{R}^d$. This leads then to following notion of continuous stable supports, which characterizes supports with respect to the continuous penalty $\Phi$. In Section 4, we relate this to the notion of discrete stable supports, which characterizes supports with respect to the combinatorial penalty $F$.

**Definition 2** (Continuous stability). We say that $J \subseteq V$ is weakly stable w.r.t. $\Phi$ if there exists $w \in \mathbb{R}^d$, supp($w$) $= J$ such that $\Phi$ is decomposable at $w$ w.r.t. $J$. Furthermore, we say that $J \subseteq V$ is strongly stable w.r.t. $\Phi$ if for all $w \in \mathbb{R}^d$ s.t. supp($w$) $\subseteq J$, $\Phi$ is decomposable at $w$ w.r.t. $J$.

Theorem [1] considers slightly more general estimators than (5) and shows that weak stability is a necessary condition for a non-zero pattern to be allowed as a solution.

**Theorem 1.** The minimizer $\hat{w}$ of $\min_{w \in \mathbb{R}^d} L(w) - z^T w + \lambda \Phi(w)$, where $L$ is a strongly-convex and smooth loss function and $z \in \mathbb{R}^d$ has a continuous density w.r.t. to the Lebesgue measure, has a weakly stable support w.r.t. $\Phi$, with probability one.

This new result extends and simplifies the result in [11] which considers the special case of quadratic loss functions and $\Phi$ being the $\ell_\infty$-convex relaxation of a submodu-
lar function. The proof we present, in the Appendix, is also shorter and simpler.

**Corollary 1.** Assume $y \in \mathbb{R}^d$ has a continuous density w.r.t to the Lebesgue measure, then the support of the minimizer $\hat{w}$ of Eq. (5) is weakly stable w.r.t $\Phi$ with probability one.

### 3.2 Adaptive estimation

Restricting the choice of regularizers in (5) to convex relaxations as surrogates to combinatorial penalties is motivated by computational tractability concerns. However, other non-convex regularizers such as $\ell_\alpha$-quasi-norms [26, 14] or more generally penalties of the form $\Phi(w) = \sum_{i=1}^d \phi(|w_i|)$, where $\phi$ is a monotone concave penalty [12, 8, 16] can be more advantageous than the convex $\ell_1$-norm. Such penalties are closer to the $\ell_0$-norm and penalize more aggressively small coefficients, thus they have a stronger sparsity-inducing effect than $\ell_1$-norm.

The authors in [24] extended such concave penalties to the $\ell_\alpha/\ell_2$- quasi-norm $\Phi(w) = \sum_{i=1}^d \|w_i\|_\alpha$ for some $\alpha \in (0, 1)$, which enforces sparsity at the group level more aggressively. We generalize this to $\Phi(|w|^\alpha)$ where $\Phi$ is any structured sparsity-inducing monotone convex regularizer.

These non-convex penalties lead to intractable estimation problems, but approximate solutions can be obtained by majorization-minimization algorithms, as suggested for e.g., in [13, 39, 5].

**Lemma 3.** Let $\Phi$ be a monotone convex function, $\Phi(|w|^\alpha)$ admits the following majorizer, $\forall w^0 \in \mathbb{R}^d$, $\Phi(|w|^\alpha) \leq (1 - \alpha)\Phi(|w^0|^\alpha) + \alpha\Phi(|w^0|^\alpha - 1 \circ |w|)$, which is tight at $w^0$.

We consider the adaptive weight estimator (6) resulting from applying a 1-step majorization-minimization to (5),

$$\min_{w \in \mathbb{R}^d} \frac{1}{2} \|y - Xw\|_2^2 + \lambda_n \Phi(|w|^\alpha - 1 \circ |w|),$$

where $w^0$ is a $\sqrt{n}$-consistent estimator to $w^*$, that is converging to $w^*$ at rate $1/\sqrt{n}$ (typically obtained from $w^0 = 1$ or ordinary least-squares).

We study sufficient support recovery and estimation consistency conditions for (6) for general convex monotone regularizers $\Phi$. Such consistency results have been established for (5), in the classical asymptotic setting, only in the special case of $\ell_1$-norm in [33] and for the (non-adaptive) estimator (5) for homogeneous convex envelopes of monotone submodular functions, for $p = \infty$ in [1] and for general $p$ in [31], in the high dimensional setting, and for latent group Lasso norm in [32], in the asymptotic setting.

Compared to prior works, the discussion of support recovery is complicated here by the fact that $\Phi$ is not necessarily a norm (e.g., if $\Phi = \Theta_p$) and only satisfies a weak notion of decomposability.

As in [33], we consider the classical asymptotic regime in which the model generating the data is of fixed finite dimension $d$ while $n \to \infty$. As before, we assume $Q > 0$ and thus the minimizer of (6) is unique, we denote it by $\hat{w}$.

The following Theorem extends the results of [33] for the $\ell_1$-norm to any normalized absolute monotone convex regularizer if the true support satisfy the sufficient condition of strong stability in Definition 2. As we previously remarked this condition is trivially satisfied for the $\ell_1$-norm.

**Theorem 2.** [Consistency and Support Recovery] Let $\Phi : \mathbb{R}^d \to \mathbb{R}_+$ be a proper normalized absolute monotone convex function and denote by $J$ the true support $J = \text{supp}(w^*)$. If $|w^*|^\alpha \in \text{int dom } \Phi$, $J$ is strongly stable with respect to $\Phi$ and $\lambda_n$ satisfies $\frac{\lambda_n}{\sqrt{n}} \to n$, $\frac{\lambda_n}{n^{1/2}} \to \infty$, then the estimator (6) is consistent and asymptotically normal, i.e., it satisfies

$$\sqrt{n}(\hat{w}_J - w^*_J) \to^d N(0, \sigma^2 J_{JJ}^{-1}),$$

and

$$P(\text{supp}(\hat{w}) = J) \to 1.$$  

Consistency results in most existing works are established under various necessary conditions on $X$, some of which are difficult to verify in practice, such as the irrepresentability condition (c.f., [38, 1, 32, 31]). Adding data-dependent weights does not require such conditions and allows recovery even in the correlated measurement matrix setup as illustrated in our numerical results (c.f., Sect. 5).

### 4 Sparsity-inducing properties of combinatorial penalties

In section 3, we derived neccessary and sufficient conditions for support recovery defined with respect to the continuous convex penalties $\Omega$ and $\Theta$. In this Section, we translate these to conditions with respect to the combinatorial penalties $F_p$ themselves. Hence, the results of this section allows one to check which supports to expect to recover, without the need to compute the corresponding convex relaxation. To that end, we introduce in Section 4.1 discrete counterparts of weak and strong stability, and show in Section 4.2 that discrete strong stability is a sufficient, and in some cases necessary, condition for support recovery.

#### 4.1 Discrete stable supports

We recall the concept of discrete stable sets [11], also referred to as flat or closed sets [27]. We refer to such sets as discrete weakly stable sets and introduce a stronger notion of discrete stability.

**Definition 3** (Discrete stability). Given a monotone set function $F : 2^V \to \mathbb{R}_+$, a set $J \subseteq V$ is said to be weakly stable w.r.t $F$ if $\forall i \in J^c, F(J \cup \{i\}) > F(J)$.
A set $J \subseteq V$ is said to be strongly stable w.r.t $F$ if $\forall A \subseteq J, \forall i \in J^c, F(A \cup \{i\}) > F(A)$.

Note that discrete stability imply in particular feasibility, i.e., $F(J) < +\infty$. Also, if $F$ is a strictly monotone function, such as the cardinality function, then all supports are stable w.r.t $F$. It is interesting to note that for monotone submodular functions, weak and strong stability are equivalent. In fact, this equivalence holds for a more general class of functions, we call $\rho$-submodular.

**Definition 4.** A function $F : 2^V \rightarrow \mathbb{R}$ is $\rho$-submodular iff
\[
\exists \rho \in (0, 1] \ s.t., \ \forall B \subseteq V, A \subseteq B, i \in B^c
\]
\[\rho[F(B \cup \{i\}) - F(B)] \leq F(A \cup \{i\}) - F(A)\]

The notion of $\rho$-submodularity is a special case of the weakly $\rho$-submodular property defined for continuous functions [17]. It is also related to the notion of weak submodularity (c.f., [7, 11]). We show in the appendix that $\rho$-submodularity is a stronger condition.

**Proposition 2.** If $F$ is a finite-valued monotone function, $F$ is $\rho$-submodular iff discrete weak stability is equivalent to strong stability.

**Example 6.** The range function $\text{range}(A) = \max(A) - \min(A) + 1$ is $\rho$-submodular with $\rho = \frac{1}{\sigma - 1}$.

### 4.2 Relation between discrete and continuous stability

This section provides several technical results relating the discrete and continuous notions of stability. It thus provides us with the necessary tools to characterize which supports can be correctly estimated w.r.t the combinatorial penalty itself, without going through its relaxations.

**Proposition 3.** Given any monotone set function $F$, all sets $J \subseteq V$ strongly stable w.r.t $F$ are also strongly stable w.r.t $\Omega_p$ and $\Theta_p$.

It follows then by Theorem [2] that discrete strong stability is a sufficient condition for correct estimation.

**Corollary 2.** If $\Phi$ is equal to $\Omega_p$ or $\Theta_p$ for $p \in (1, \infty)$ and $\text{supp}(w^*) = J$ is strongly stable w.r.t $F$, then Theorem [2] holds, i.e., the adaptive estimator (AE) is consistent and correctly recovers the support. This also holds for $p = \infty$ if we further assume that $\|w^*\|_\infty < 1$.

Furthermore, if $F$ is $\rho$-submodular, then by Proposition [2] it is enough for $\text{supp}(w^*) = J$ to be weakly stable w.r.t $F$ for Corollary [2] to hold. Conversely, Proposition [4] below shows that discrete strong stability is also a necessary condition for continuous strong stability, in the case where $p = \infty$ and $F$ is equal to its LCE.

**Proposition 4.** If $F = F_\infty$ and $J$ is strongly stable w.r.t $\Omega_\infty$, then $J$ is strongly stable w.r.t $F$. Similarly, for any monotone $F$, if $J$ is strongly stable w.r.t $\Theta_\infty$, then $J$ is strongly stable w.r.t $F$.

Finally, in the special case of monotone submodular function, the following Corollary [3] along with Proposition [5] demonstrates that all definitions of stability become equivalent. We thus recover the result in [1] showing that discrete weakly stable supports correspond to the set of allowed sparsity patterns for monotone submodular functions.

**Corollary 3.** If $F$ is monotone submodular and $J$ is weakly stable w.r.t $\Omega_\infty = \Theta_\infty$ then $J$ is weakly stable w.r.t $F$.

### 4.3 Examples

We highlight in this section what are the supports recovered by the adaptive estimator (AE) with the homogenous convex relaxation $\Omega_p$ and non-homogeneous convex relaxation $\Theta_p$ of some examples of structure priors. For simplicity, we will focus on the case $p = \infty$. Also in all the examples we consider below, weak and strong discrete stability are equivalent, so we omit the weak/strong specification. Note that it is desirable that the regularizer used enforces the recovery of only the non-zero patterns satisfying the desired structure.

**Monotone submodular functions:** As discussed above, for this class of functions, all stability definitions are equivalent and $\Omega_\infty = \Theta_\infty = f_L$. As a result, AE recovers any discrete stable non-zero pattern. This includes the following examples (c.f., [3] for further examples).

- **Cardinality:** As a strictly monotone function, all supports are stable w.r.t to it. Thus AE recovers all non-zero patterns with $\Omega_\infty$ and $\Theta_\infty$, given by the $\ell_1$-norm.

- **Overlap count function:** $F_G(A) = \sum_{G \in G, G \ni A \neq \emptyset} d_G$ where $G$ is a collection of predefined groups with associated weights. $\Omega_\infty$ and $\Theta_\infty$ are given by the $\ell_1/\ell_\infty$-group Lasso norm, and stable patterns are complements of union of groups. For example, for hierarchical groups (i.e., groups consisting of each node and its descendents on a tree), AE recovers rooted connected tree supports.

- **Modified range function:** The range function can be transformed into a submodular function, if scaled by a constant as suggested in [1], yielding the monotone submodular function $F_{\Omega_d}(A) = d - 1 + \text{range}(A)$, $\forall A \neq \emptyset$ and $F_{\Omega_d}(\emptyset) = 0$. This can actually be written as an instance of $F_G$, with groups defined as $G = \{[1, k] : 1 \leq k \leq d\} \cup \{[k, d] : 1 \leq k \leq d\}$. This norm was proposed to induce interval patterns by [23], and indeed its stable patterns are interval supports. We will compare this function in the experiments with the direct convex relaxations of the range function.

**Range function:** The range function is $\frac{1}{\sigma - 1}$-submodular,
as discussed in Section 4.3, the regularization, on the quality of support recovery.

Thus its discrete strongly and weakly stable supports are identical and they correspond to interval supports. As a result, AE recovers interval supports with $\Theta_\infty$. On the other hand, since the homogeneous LCE of the range function is the cardinality, AE recovers all supports with $\Omega_\infty$.

**Down monotone structures:** Functions of the form $F(A) = |A| + \ell_{A \in \mathcal{A}}(A)$, where $\mathcal{A}$ is down-monotone, also have their discrete strongly and weakly stable supports identical and given by the feasible set $\mathcal{A}$. These structures include the dispersive and graph models discussed in examples 4 and 5. Since their homogeneous LCE is also the cardinality, then AE recovers all supports with $\Omega_\infty$, and only feasible supports with $\Theta_\infty$.

## 5 Numerical Illustration

To illustrate the results presented in this paper, we consider the problem of estimating the support of a parameter vector $w^* \in \mathbb{R}^d$ whose support is an interval. It is natural then to choose as combinatorial penalty the range function whose stable supports are intervals. We aim to study the effect of adaptive weights, as well as the effect of the choice of homogeneous vs. non-homogeneous convex relaxation for the problem of estimating the support of a parameter vector $w^*$, along the regularization path, averaged over 5 runs.

![Support Recovery Error, $\rho = 0$](image1)

![Estimation Error, $\rho = 0$](image2)

![Support Recovery Error, $\rho = 0.5$](image3)

![Estimation Error, $\rho = 0.5$](image4)

Figure 3: (Left column) Best Hamming distance and (Right column) best least square error to the true vector $w^*$, along the regularization path, averaged over 5 runs.

![Support Recovery Error, $\rho = 0$](image5)

![Support Recovery Error, $\rho = 0.5$](image6)

Thus its discrete strongly and weakly stable supports are identical and they correspond to interval supports. As a result, AE recovers interval supports with $\Theta_\infty$. On the other hand, since the homogeneous LCE of the range function is the cardinality, AE recovers all supports with $\Omega_\infty$.

![Estimation Error, $\rho = 0$](image7)

![Estimation Error, $\rho = 0$](image9)

![Estimation Error, $\rho = 0.5$](image10)

We observe that the adaptive weight scheme helps in support recovery, especially in the correlated design setting. Indeed, Lasso is only guaranteed to recover the support under an “irrepresentability condition” [38]. This is satisfied with high probability only in the non-correlated design. On the other hand, adaptive weights allow us to recover any strongly stable support, without any additional condition, as shown in Theorem 2. The $\ell_1/\ell_\infty$-norm performs poorly in this setup. In fact, the modified range function $F^{mr}$ introduced a gap of $d$ between non-empty sets and the empty set. This leads to the undesirable behavior, already documented in [1], of adding all the variables in one step, as opposed to gradually. Adaptive weights seem to correct for this effect, as seen by the significant improvement in performance. Finally, note that choosing the “tighter” non-homogeneous convex relaxation leads to better support recovery. Indeed, $\Theta_\infty$ performs better than $\ell_1$-norm in all setups.

## 6 Conclusion

We presented an analysis of homogeneous and non-homogeneous convex relaxations of $\ell_p$-regularized combinatorial penalties. Our results show that structure encoded by submodular priors can be equally well expressed by both relaxations, while the non-homogeneous relaxation is able to express the structure of more general monotone set functions. We also identified necessary and sufficient stability conditions on the supports to be correctly recovered. We proposed an adaptive weight scheme that is guaranteed to recover supports that satisfy the sufficient stability conditions, in the asymptotic setting, even under correlated design matrix.

Convex relaxations of combinatorial penalties.

7 Appendix

7.1 Variational forms of convex envelopes (Proof of lemma 2 and Remark 1)

In this section, we recall the different variational forms of the homogeneous convex envelope derived in [31] and derive similar variational forms for the non-homogeneous convex envelope, which includes the ones stated in lemma 2. These variational forms will be needed in some of our proofs below.

**Lemma 4.** The homogeneous convex envelope $\Omega_p$ of $F_p$ admits the following variational forms.

\[
\Omega_\infty(w) = \min_{\alpha} \left\{ \sum_{S \subseteq V} \alpha_S F(S) : \sum_{S \subseteq V} \alpha_S 1_S \geq |w|, \alpha_S \geq 0 \right\}. \tag{9}
\]

\[
\Omega_p(w) = \min_{\nu} \left\{ \sum_{S \subseteq V} F(S)^{1/q} \|u^S\|_p : \sum_{S \subseteq V} v^S = |w|, \text{supp}(v^S) \subseteq S \right\}. \tag{10}
\]

\[
= \max_{\kappa \in \mathbb{R}_+^d} \sum_{i=1}^d \kappa_i^{1/q} |w_i| \text{ s.t. } \kappa(A) \leq F(A), \forall A \subseteq V. \tag{11}
\]

\[
= \inf_{\eta \in \mathbb{R}_+^d} \frac{1}{p} \sum_{j=1}^d \frac{|w_j|^p}{\eta_j^{p-1}} + \frac{1}{q} \Omega_\infty(\eta). \tag{12}
\]

The non-homogeneous convex envelope of a set function $F$, over the unit $\ell_\infty$-ball was derived in [10], where it was shown that $\Theta_p(w) = \inf_{\eta \in [0,1]^d} \left\{ \Phi(\eta) : \eta \geq |w| \right\}$ where $\Phi$ is any proper, l.s.c convex extension of $F$ (c.f., Lemma 1 [10]). A natural choice for $\Phi$ is the convex closure of $F$, which corresponds to the tightest convex extension of $F$ on $[0,1]^d$. We recall the two equivalent definitions of convex closure, which we have adjusted to allow for infinite values.

**Definition 5 (Convex Closure; c.f., [9, Def. 3.1]).** Given a set function $F : 2^V \rightarrow \mathbb{R}$, the convex closure $f^- : [0,1]^d \rightarrow \mathbb{R}$ is the point-wise largest convex function from $[0,1]^d$ to $\mathbb{R}$ that always lowerbounds $F$.

**Definition 6 (Equivalent definition of Convex Closure; c.f., [35, Def. 1] and [9, Def. 3.2]).** Given any set function $f : \{0,1\}^n \rightarrow \mathbb{R}$, the convex closure of $f$ can equivalently be defined $\forall w \in [0,1]^n$ as:

\[
f^-(w) = \inf \left\{ \sum_{S \subseteq V} \alpha_S F(S) : w = \sum_{S \subseteq V} \alpha_S 1_S, \sum_{S \subseteq V} \alpha_S = 1, \alpha_S \geq 0 \right\}.
\]

It is interesting to note that $f^-(w) = f_L(w)$ where $f_L$ is Lovász extension iff $F$ is a submodular function [35].

The following lemma derive variational forms of $\Theta_p$ for any $p \geq 1$ that parallel the ones known for the homogeneous envelope.

**Lemma 5.** The non-homogeneous convex envelope $\Theta_p$ of $F_p$ admits the following variational forms.

\[
\Theta_\infty(w) = \inf \left\{ \sum_{S \subseteq V} \alpha_S F(S) : \sum_{S \subseteq V} \alpha_S 1_S \geq |w|, \sum_{S \subseteq V} \alpha_S = 1, \alpha_S \geq 0 \right\}. \tag{13}
\]

\[
\Theta_p(w) = \max_{\kappa \in \mathbb{R}_+^d} \sum_{j=1}^d \psi_j(\kappa_j, w_j) + \min_{\nu \in \mathbb{R}_+^d} F(S) - \kappa(S), \forall w \in \text{dom}(\Theta_p(w)). \tag{14}
\]

\[
= \inf_{\eta \in [0,1]^d} \frac{1}{p} \sum_{j=1}^d \frac{|w_j|^p}{\eta_j^{p-1}} + \frac{1}{q} f^-(\eta), \tag{15}
\]

where $\text{dom}(\Theta_p) = \{w \exists \eta \in [0,1]^d \text{ s.t supp}(w) \subseteq \text{supp}(\eta), \eta \in \text{dom}(f^-)\}$, and where we define

\[
\psi_j(\kappa_j, w_j) := \begin{cases} 
\kappa_j^{1/q} |w_j| & \text{if } |w_j| \leq \kappa_j^{1/p}, \kappa_j \geq 0 \\
\frac{1}{p} |w_j|^p + \frac{1}{q} \kappa_j & \text{otherwise}.
\end{cases}
\]

If $F$ is monotone, $\Theta_\infty = f^-$, then we can replace $f^-$ by $\Theta_\infty$ in (15) and we can restrict $\kappa \in \mathbb{R}_+^d$ in (14).

To prove the variational form (13) in Lemma 5, we need to show first the following property of $f^-$. 

**Convex relaxations of combinatorial penalties.**

**Proposition 5** (c.f., [9] Prop. 3.23). The minimum values of a proper set function $F$ and its convex closure $f^-$ are equal, i.e.,

$$\min_{w \in [0,1]^d} f^-(w) = \min_{S \subseteq V} F(S)$$

If $S$ is a minimizer of $f(S)$, then $\mathbb{1}_S$ is a minimizer of $f^-$. Moreover, if $w$ is a minimizer of $f^-$, then every set in the support of $\alpha$, where $f^-(w) = \sum_{S \subseteq V} \alpha_S F(S)$, is a minimizer of $F$.

**Proof.** First note that, $\{0,1\}^d \subseteq [0,1]^d$ implies that $f^-(w^*) \leq F(S^*)$. On the other hand, $f^-(w^*) = \sum_{S \subseteq V} \alpha^*_S F(S) \geq \sum_{S \subseteq V} \alpha^*_S F(S) = F(S^*)$. The rest of the proposition follows directly.

Given the choice of the extension $f = f^-$, the variational form (13) of $\Theta_\infty$ given in lemma 5 follows directly from definition [4] and proposition [5] as shown in the following corollary.

**Corollary 4.** Given any set function $F : 2^V \rightarrow \mathbb{R}_+$ and its corresponding convex closure $f^-$, the convex envelope of $F(\text{supp}(w))$ over the unit $\ell_\infty$-ball is given by

$$\Theta_\infty(w) = \inf_{\alpha} \{ \sum_{S \subseteq V} \alpha_S F(S) : \sum_{S \subseteq V} \alpha_S \mathbb{1}_S \geq |w|, \sum_{S \subseteq V} \alpha_S = 1, \alpha_S \geq 0 \}.$$

$$= \inf_{w} \{ \sum_{S \subseteq V} F(S) \|v^S\|_\infty : \sum_{S \subseteq V} v^S = |w|, \sum_{S \subseteq V} \|v^S\|_\infty = 1, \text{supp}(v^S) \subseteq S \}.$$

**Proof.** $f^-$ satisfies the first 2 assumptions required in Lemma 1 of [10], namely, $f^-$ is a lower semi-continuous convex extension of $F$ which satisfies

$$\max_{S \subseteq V} m(S) - F(S) = \max_{w \in [0,1]^d} m^T w - f^-(w), \forall m \in \mathbb{R}_d^d$$

To see this note that $m^T w^* - f^-(w^*) = \sum_{S \subseteq V} \alpha^*_S (m^T \mathbb{1}_S - F(S)) \geq \sum_{S \subseteq V} \alpha^*_S (m^T \mathbb{1}_S - F(S^*)) = m(S^*) - F(S^*)$.

Note that $\text{dom}(\Theta_\infty) = \{ w : \exists \eta \in [0,1]^d \cap \text{dom}(f^-), \eta \geq |w| \}$. Note also that $\Theta_\infty$ is monotone even if $F$ is not. On the other hand, if $F$ is monotone, then $f^-$ is monotone on $[0,1]^d$ and $\Theta_\infty(w) = f^- (|w|)$. Then the proof of remark [1] follows, since if $F$ is a monotone submodular function and $f_L$ is its Lovász extension, then $\Theta_\infty(w) = f^- (|w|) = f_L (|w|) = \Omega_\infty(w), \forall w \in [-1,1]^d$, where the last equality was shown in [1].

Next, we derive the convex relaxation of $F_p$ for a general $p \geq 1$.

**Proposition 6.** Given any set function $F : 2^V \rightarrow \mathbb{R}_+$ and its corresponding convex closure $f^-$, the convex envelope of $F_{\mu\lambda}(w) = \mu F(\text{supp}(w)) + \lambda \|w\|_p^p$ is given by

$$\Theta_p(w) = \inf_{\eta \in [0,1]^d} \lambda \sum_{j=1}^d \frac{|w_j|^p}{\eta_j^{p-1}} + \mu F^-(\eta).$$

**Note that** $\text{dom}(\Theta_p) = \{ w : \exists \eta \in [0,1]^d \cap \text{supp}(w) \subseteq \text{supp}(\eta), \eta \in \text{dom}(f^-) \}$.  

**Proof.** Given any proper l.s.c. convex extension $f$ of $F$, we have:

First for the case where $p = 1$:

$$F_{\mu\lambda}^*(s) = \sup_{w \in \mathbb{R}_n} w^T s - \mu F(\text{supp}(w)) - \lambda \|w\|_1$$

$$= \sup_{\eta \in [0,1]^d} \sup_{|\text{supp}(w)| \geq \eta \text{ s.t. } \text{sign}(w) = \text{sign}(\eta) \text{ and } w \in \mathbb{R}_n} |w|^T (|s| - \lambda \mathbb{1}) - \mu F(\eta)$$

$$= t\{s \leq \lambda \mathbb{1}\}(s) - \inf_{\eta \in [0,1]^d} \mu F(\eta).$$
Hence $F_{p, \lambda}^*(w) = \lambda \|w\|_1 + \inf_{\eta \in \{0,1\}^d} \lambda F(\eta)$. For the case $p \in (1, \infty)$.

\[
F_{p, \lambda}^*(s) = \sup_{w \in \mathbb{R}^d} w^T s - \mu F(\text{supp}(w)) - \lambda \|w\|_p^p
= \sup_{\eta \in \{0,1\}^d} \sup_{\text{supp}(w) = \eta} |w|^T |s| - \lambda \|w\|_p^p - \mu F(\eta)
= \sup_{\eta \in \{0,1\}^d} \frac{\lambda(p-1)}{(\lambda p)^q} |s|^q - \mu F(\eta)
\]

\[
(\|s\| = \lambda p |x_i^*|^{p-1}, \forall \eta_i \neq 0)
\]

\[
(\|s\| = \lambda p |x_i^*|^{p-1}, \forall \eta_i \neq 0)
\]

We denote $\hat{\lambda} = \frac{\lambda(p-1)}{(\lambda p)^q}$.

\[
F_{p, \lambda}^*(w) = \sup_{s \in \mathbb{R}^d} w^T s - F_{p, \lambda}^*(s)
= \sup_{s \in \mathbb{R}^d} \min_{\eta \in \{0,1\}^d} s^T w - \hat{\lambda} \eta^T |s|^q + \mu f^-(\eta)
= \inf_{\eta \in \{0,1\}^d} \sup_{s \in \mathbb{R}^d} |s|^T |w| - \hat{\lambda} \eta^T |s|^q + \mu f^-(\eta)
= \inf_{\eta \in \{0,1\}^d} \lambda(|w|^p)^T \eta^{1-p} + \mu f^-(\eta),
\]

where the last equality holds since $|w_i| = \hat{\lambda} \eta_i |s_i|^q - 1, \forall \eta_i \neq 0$, otherwise $s_i^* = 0$ if $w_i = 0$ and $\infty$ otherwise. ($\ast$) holds by Sion’s minimax theorem [34, Corollary 3.3]. Note then that the minimizer $\eta^*$. (if it exists) satisfies $\text{supp}(w) \subseteq \text{supp}(\eta^*)$. Finally, note that if we take the limit as $p \to \infty$, we recover $\Theta_\infty = \inf_{\eta \in \{0,1\}^d} \{f^-(\eta) : \eta \geq |x|\}$.

The variational form [15] given in lemma [5] follows from proposition 6 for the choice $\mu = \frac{1}{q}, \lambda = \frac{1}{p}$.

The following proposition derives the variational form [4] for $p = \infty$.

**Proposition 7.** Given any set function $F : 2^V \to \mathbb{R} \cup \{+\infty\}$, and its corresponding convex closure $f^-, \Theta_\infty$ can be written $\forall w \in \text{dom}(\Theta_\infty)$ as

\[
\Theta_\infty(w) = \max_{\kappa \in \mathbb{R}^+_d} \{\kappa^T |w| + \min_{S \subseteq \text{supp}(w)} F(S) - \kappa(S)\}
= \max_{\kappa \in \mathbb{R}^+_d} \{\kappa^T |w| + \min_{S \subseteq \text{supp}(w)} F(S) - \kappa(S)\}
\]

(if $F$ is monotone)

Similarly $\forall w \in \text{dom}(f^-)$ we can write

\[
f^-(w) = \max_{\kappa \in \mathbb{R}^+_d} \{\kappa^T |w| + \min_{S \subseteq \text{supp}(w)} F(S) - \kappa(S)\}
= \Theta_\infty(w) = \max_{\kappa \in \mathbb{R}^+_d} \{\kappa^T |w| + \min_{S \subseteq \text{supp}(w)} F(S) - \kappa(S)\}
\]

(if $F$ is monotone)

\[
\Theta_\infty(w) = \min_{\alpha \subseteq V} \sum_{S \subseteq \alpha} \alpha_S F(S) + \sum_{S \subseteq \alpha} \alpha_S \mathbb{1}_S \geq |w|, \sum_{S \subseteq \alpha} \alpha_S = 1, \alpha_S \geq 0}.\]

\[
= \min_{\alpha \subseteq V} \max_{\rho \in \mathbb{R}, \kappa \in \mathbb{R}^+_d} \{\sum_{S \subseteq \alpha} \alpha_S F(S) + \kappa^T |w| - \sum_{S \subseteq \alpha} \alpha_S \mathbb{1}_S\} + \rho(1 - \sum_{S \subseteq \alpha} \alpha_S).\]

\[
= \max_{\rho \in \mathbb{R}, \kappa \in \mathbb{R}^+_d} \min_{\alpha \subseteq V} \{\kappa^T |w| + \sum_{S \subseteq \alpha} \alpha_S (F(S) - \kappa^T \mathbb{1}_S - \rho) + \rho\}.\]

\[
= \max_{\rho \in \mathbb{R}, \kappa \in \mathbb{R}^+_d} \{\kappa^T |w| + \sum_{S \subseteq \alpha} \alpha_S (F(S) - \kappa^T \mathbb{1}_S + \rho)\}.\]

\[
= \max_{\kappa \in \mathbb{R}^+_d} \{\kappa^T |w| + \min_{S \subseteq \text{supp}(w)} F(S) - \kappa(S)\}.\]
Let \( J = \text{supp}(|w|) \) then \( \kappa^*_p = 0 \). Then for monotone functions \( F(S) - \kappa^*(S) \geq F(S \cap J) - \kappa^*(S) \), so we can restrict the minimum to \( S \subseteq J \). The same proof holds for \( f^- \), with the Lagrange multiplier \( \kappa \in \mathbb{R}^d \) not constrained to be positive.

The following Corollary derives the variational form \([14]\) for \( p \in [1, \infty] \).

**Corollary 5.** Given any set function \( F : 2^V \to \mathbb{R} \cup \{+\infty\} \), \( \Theta_p \) can be written \( \forall w \in \text{dom}(\Theta_p) \) as

\[
\Theta_p(w) = \max_{\kappa \in \mathbb{R}^d} \sum_{j=1}^d \psi_j(\kappa_j, w_j) + \min_{S \subseteq V} F(S) - \kappa(S).
\]

\[
= \max_{\kappa \in \mathbb{R}^d} \sum_{j=1}^d \psi_j(\kappa_j, w_j) + \min_{S \subseteq V} F(S) - \kappa(S).
\]

where

\[
\psi_j(\kappa_j, w_j) := \begin{cases} \kappa_j^1/|w_j| & \text{if } |w_j| \leq \kappa_j^{1/p}, \kappa_j \geq 0 \\ \frac{1}{p}|w_j|^p + \frac{1}{q}\kappa_j & \text{otherwise} \end{cases}
\]

Proof. By Propositions\([6, 7]\) we have \( \forall w \in \text{dom}(\Theta_p) \), i.e., \( \exists \eta \in [0, 1]^d \), s.t. \( \text{supp}(w) \subseteq \text{supp}(\eta) \), \( \eta \in \text{dom}(f^-) \),

\[
\Theta_p(w) = \inf_{\eta \in [0, 1]^d} \frac{1}{p} \sum_{j=1}^d \frac{|w_j|^p}{\eta_j} + \frac{1}{q} f^-(\eta)
\]

\[
= \inf_{\eta \in [0, 1]^d} \frac{1}{p} \sum_{j=1}^d \frac{|w_j|^p}{\eta_j} + \frac{1}{q} \max_{\rho \in \mathbb{R}^k, \kappa \in \mathbb{R}^d} \{\kappa^T \eta + \rho : F(S) \geq \kappa^T \mathbb{1}_S + \rho \}.
\]

\[
= \max_{\rho \in \mathbb{R}^k, \kappa \in \mathbb{R}^d} \inf_{\eta \in [0, 1]^d} \left\{ \frac{1}{p} \sum_{j=1}^d \frac{|w_j|^p}{\eta_j} + \frac{1}{q} \kappa^T \eta + \rho : F(S) \geq \kappa^T \mathbb{1}_S + \rho \right\}.
\]

(*) holds by Sion’s minimax theorem \([34]\) Corollary 3.3. Note also that

\[
\inf_{\eta_j \in [0, 1]} \frac{1}{p} \frac{|w_j|^p}{\eta_j} + \frac{1}{q} \kappa_j \eta_j = \begin{cases} \kappa_j^{1/q} |w_j| & \text{if } |w_j| \leq \kappa_j^{1/p}, \kappa_j \geq 0 \\ \frac{1}{p} |w_j|^p + \frac{1}{q}\kappa_j & \text{otherwise} \end{cases} := \psi_j(\kappa_j, w_j)
\]

where the minimum is \( \eta_j^* = 1 \) if \( \kappa_j \leq 0 \). If \( \kappa_j \geq 0 \), the infimum is zero if \( w_j = 0 \). Otherwise, the minimum is achieved at \( \eta_j^* = \min\left\{ \frac{|w_j|}{\kappa_j^{1/p}}, 1 \right\} \) (if \( \kappa_j = 0, \eta_j^* = 1 \)). Hence,

\[
\Theta_p(w) = \max_{\kappa \in \mathbb{R}^d} \sum_{j=1}^d \psi_j(\kappa_j, w_j) + \min_{S \subseteq V} F(S) - \kappa(S).
\]

\boxed{}

### 7.2 Necessary conditions for support recovery (Proof of Theorem\([1]\))

Before proving Theorem\([1]\) we need the following technical Lemma.

**Lemma 6.** Given \( J \subseteq V \) and a vector \( w \) s.t. \( \text{supp}(w) \subseteq J \), if \( \Phi \) is not decomposable at \( w \) w.r.t \( J \), then \( \exists i \in J^c \) such that the \( i \)-th component of all subgradients at \( w \) is zero; \( 0 = \partial \Phi(w)[i] \).

Proof. If \( \Phi \) is not decomposable at \( w \) and \( 0 \neq \partial \Phi(w)[i], \forall i \in J^c \), then \( \forall M_j > 0, \exists \Delta > 0, \sup(\Delta) \subseteq J^c \) s.t., \( \Phi(w + \Delta) < \Phi(w) + M_j \|\Delta\|_\infty \). In particular, we can choose \( M_j = \inf_{i \in J^c, v \in \partial \Phi(w)[i]} \|v\|_\infty > 0 \), if the inequality holds for some \( \Delta \neq 0 \), then let \( i_{\max} \) denote the index where \( \|\Delta\|_\infty = \|\Delta\|_\infty \). Then given any \( v \in \partial \Phi(w) \) s.t. \( v_{i_{\max}} \neq 0 \), we have

\[
\Phi(w + \|\Delta\|_\infty \mathbb{1}_{i_{\max}}) \leq \Phi(w + \Delta) < \Phi(w) + M_j \|\Delta\|_\infty \leq \Phi(w) + \langle v, \|\Delta\|_\infty \mathbb{1}_{i_{\max}} \text{sign}(v_{i_{\max}}) \rangle \leq \Phi(w + \|\Delta\|_\infty \mathbb{1}_{i_{\max}})
\]

which leads to a contradiction.
Theorem 1. The minimizer \( \hat{w} \) of \( \min_{w \in \mathbb{R}^d} L(w) - z^T w + \lambda \Phi(w) \), where \( L \) is a strongly-convex and smooth loss function and \( z \in \mathbb{R}^d \) has a continuous density w.r.t. to the Lebesgue measure, has a weakly stable support w.r.t. \( \Phi \), with probability one.

Proof. We will show in particular that \( \hat{w} \) minimizes \( \Phi \) w.r.t. \( \text{supp}(\hat{w}) \). Since \( L \) is strongly-convex, given \( z \) the corresponding minimizer \( \hat{w} \) is unique, then the function \( h(z) := \arg \min_{w \in \mathbb{R}^d} L(w) - z^T w + \lambda \Phi(w) \) is well defined. We want to show that

\[
P(\forall z, \Phi \text{ is decomposable at } h(z) \text{ w.r.t } \text{supp}(h(z))) = 1 - P(\exists z, \text{s.t.}, h(z) \text{ is not decomposable at } \Phi(h(z)) \text{ w.r.t } \text{supp}(h(z))) \geq 1 - P(\exists z, \text{s.t.}, \exists i \in (\text{supp}(h(z)))^c, [\partial \Phi(h(z))]_i = 0) \tag{8}
\]

by lemma 6. If \( z \in V \), we show that the set \( S_i := \{ z : i \in (\text{supp}(h(z)))^c, [\partial \Phi(h(z))]_i = 0 \} \) has measure zero. Then, taking the union of the finitely many sets \( S_i, \forall i \in V \), all of zero measure, we have \( P(\exists z, \text{s.t.}, \exists i \in (\text{supp}(h(z)))^c, [\partial \Phi(h(z))]_i = 0) = 0 \).

To show that the set \( S_i \) has measure zero, let \( z_1, z_2 \in S_i \) and denote by \( \mu > 0 \) the strong convexity constant of \( L \). We have by convexity of \( \Phi \):

\[
\left( (z_1 - \nabla L(h(z_1))) - (z_2 - \nabla L(h(z_2))) \right)^T (h(z_1) - h(z_2)) \geq 0
\]

\[
(z_1 - z_2)^T (h(z_1) - h(z_2)) \geq (\nabla L(h(z_1)) - \nabla L(h(z_2)))^T (h(z_1) - h(z_2))
\]

\[
(z_1 - z_2)^T (h(z_1) - h(z_2)) \geq \mu \|h(z_1) - h(z_2)\|^2_2
\]

\[
\frac{1}{\mu} \|z_1 - z_2\|_2 \geq \|h(z_1) - h(z_2)\|_2
\]

Thus \( h(z) \) is a deterministic Lipschitz-continuous function of \( z \). Let \( J = \text{supp}(h(z)) \), then by optimality conditions \( z_J - \nabla L(h(z_J)) \in \partial \Phi(h(z_J)) \) (since \( h(z) = h(z_J) \)), then \( z_J - \nabla L(h(z_J)) \) is not decomposable at \( h(z) \) which only happen with zero measure.

\[\square\]

7.3 Sufficient conditions for support recovery (Proof of Lemma 3 and Theorem 2)

Lemma 3. Let \( \Phi \) be a monotone convex function, \( \Phi(|w|^\alpha) \) admits the following majorizer, \( \forall w^0 \in \mathbb{R}^d, \Phi(|w|^\alpha) \leq (1 - \alpha)\Phi(|w^0|^\alpha) + \alpha \Phi(|w^0|^{\alpha-1} \circ |w|) \), which is tight at \( w^0 \).

Proof. The function \( w \rightarrow w^\alpha \) is concave on \( \mathbb{R}_+ \setminus \{0\} \), hence

\[
|w_j|^\alpha \leq |w_j^0|^\alpha + \alpha |w_j^0|^\alpha - 1 (|w_j| - |w_j|^0) \\
|w_j|^\alpha \leq (1 - \alpha)|w_j^0|^\alpha + |w_j^0|^\alpha - 1 |w_j| \\
\Phi(|w|^\alpha) \leq \Phi((1 - \alpha)|w|^0|^\alpha + \alpha |w^0|^{\alpha-1} \circ |w|) \tag{by monotonicity}
\]

\[
\Phi(|w|^\alpha) \leq (1 - \alpha)\Phi(|w^0|^\alpha) + \alpha \Phi(|w^0|^{\alpha-1} \circ |w|) \tag{by convexity}
\]

If \( w_j = 0 \) for any \( j \), the upper bound goes to infinity and hence it still holds.

\[\square\]

Theorem 2. [Consistency and Support Recovery] Let \( \Phi : \mathbb{R}^d \rightarrow \mathbb{R}_+ \) be a proper normalized absolute monotone convex function and denote by \( J \) the true support \( J = \text{supp}(w^*) \). If \( |w^*|^\alpha \in \text{int dom } \Phi \), \( J \) is strongly stable with respect to \( \Phi \) and \( \lambda_n \) satisfies \( \frac{\lambda_n}{\sqrt{n}} \rightarrow 0, \frac{\lambda_n}{n^{1/2}} \rightarrow \infty \), then the estimator (6) is consistent and asymptotically normal, i.e., it satisfies

\[
\sqrt{n}(\hat{w}_J - w^*_J) \overset{d}{\rightarrow} \mathcal{N}(0, \sigma^2 Q_{JJ}^{-1}) \tag{7}
\]

and

\[
P(\text{supp}(\hat{w}) = J) \rightarrow 1. \tag{8}
\]
Proof. We will follow the proof in [38]. We write \( \hat{w} = w^* + \frac{\hat{w}}{\sqrt{n}} \) and \( \Psi_n(u) = \frac{1}{2} \| y - X(w^* + \frac{u}{\sqrt{n}}) \|_2^2 + \lambda_n \Phi(c \circ |w^* + \frac{u}{\sqrt{n}}|) \), where \( c = |w^0|^{\alpha - 1} \). Then \( \hat{u} = \arg \min_{u \in \mathbb{R}^d} \Psi_n(u) \). Let \( V_n(u) = \Psi_n(u) - \Psi_n(0) \), then

\[
V_n(u) = \frac{1}{2} u^T Q u - \epsilon^T X u + \lambda_n \left( \Phi(c \circ |w^* + \frac{u}{\sqrt{n}}|) - \Phi(c \circ |w^*|) \right)
\]

Since \( w^0 \) is a \( \sqrt{n} \)-consistent estimator to \( w^* \), then \( \sqrt{n} w^0_{j^*} = O_p(1) \) and \( n^{\frac{\alpha - 2}{2}} c^{-1}_{j^*} = O_p(1) \). Since \( \mathcal{X}_{\mathcal{W} \cap J} \rightarrow \infty \), by stability of \( J \), we have

\[
\lambda_n \left( \Phi(c \circ |w^* + \frac{u}{\sqrt{n}}|) - \Phi(c \circ |w^*|) \right) = \lambda_n \left( \Phi(c_J \circ |w^*_{j^*} + \frac{u_{j^*}}{\sqrt{n}}|) + c_{j^*} \circ \frac{|u_{j^*}|}{\sqrt{n}} - \Phi(c_J \circ |w^*|) \right)
\]

\[
\geq \lambda_n \left( \Phi(c_J \circ |w^*_{j^*} + \frac{u_{j^*}}{\sqrt{n}}|) + M_J ||c_{j^*} \circ \frac{|u_{j^*}|}{\sqrt{n}}||_{\infty} - \Phi(c_J \circ |w^*|) \right)
\]

\[
= \lambda_n \left( \Phi(c_J \circ |w^*_{j^*} + \frac{u_{j^*}}{\sqrt{n}}|) - \Phi(c_J \circ |w^*|) \right) + M_J ||\lambda_n n^{-\alpha/2} n^{\frac{\alpha - 1}{2}} c_{j^*} \circ |u_{j^*}|||_{\infty}
\]

\[
P \rightarrow \infty \quad \text{if} \quad u_{j^*} \neq 0
\]  

(16)

Otherwise, if \( u_{j^*} = 0 \), we argue that

\[
\lambda_n \left( \Phi(c \circ |w^* + \frac{u}{\sqrt{n}}|) - \Phi(c \circ |w^*|) \right) = \lambda_n \left( \Phi(c_J \circ |w^*_{j^*} + \frac{u_{j^*}}{\sqrt{n}}|) - \Phi(c_J \circ |w^*|) \right) \overset{P}{\rightarrow} 0.
\]  

(17)

To see this note first that since \( w^0 \) is a \( \sqrt{n} \)-consistent estimator to \( w^* \), then \( c_J = |w^0_{j^*}|^{\alpha - 1} \overset{P}{\rightarrow} |w^*_{j^*}|^{\alpha - 1}, c_J \circ |w^*_{j^*}| \overset{P}{\rightarrow} |w^*_{j^*}|^{\alpha} \) and \( c_J \circ |w^*_{j^*} + \frac{u_{j^*}}{\sqrt{n}}| \overset{P}{\rightarrow} |w^*_{j^*}|^{\alpha} \). Then by the assumption \( |w^*|^p \in \text{int dom } \Phi \), we have that both \( c_J \circ |w^*_{j^*} + \frac{u_{j^*}}{\sqrt{n}}| \in \text{int dom } \Phi \) with probability going to one. By convexity, we then have:

\[
\lambda_n \left( \Phi(c_J \circ |w^*_{j^*} + \frac{u_{j^*}}{\sqrt{n}}|) - \Phi(c_J \circ |w^*|) \right) = \langle \nabla \Phi(c_J \circ |w^*|), \lambda_n \frac{u_{j^*}}{\sqrt{n}} \rangle
\]

\[
\lambda_n \left( \Phi(c_J \circ |w^*_{j^*} + \frac{u_{j^*}}{\sqrt{n}}|) - \Phi(c_J \circ |w^*|) \right) \leq \langle \nabla \Phi(c_J \circ |w^*|), \lambda_n \frac{u_{j^*}}{\sqrt{n}} \rangle
\]

where \( \nabla \Phi(w) \) denotes a subgradient of \( \Phi \) at \( w \).

For all \( w \in \text{int dom } \Phi \) where \( \Phi \) is convex, monotone and normalized, we have that \( ||z||_{\infty} < \infty, \forall z \in \partial \Phi(w) \). To see this, note that since \( w \in \text{int dom } \Phi \), \( \exists \delta > 0 \) s.t. \( \forall w' \in B_{\delta}(w), \Phi(w') < +\infty \). Let \( w' = w + \text{sign}(z) I_{i_{\max}} \delta \), where \( i_{\max} \) denotes the index where \( |z|_{i_{\max}} = ||z||_{\infty} \) then by convexity we have

\[
\Phi(w') \geq \Phi(w) + \langle z, w' - w \rangle, \quad \forall z \in \partial \Phi(w)
\]

\[
+\infty > \Phi(w') \geq ||z||_{\infty} \delta, \quad \forall z \in \partial \Phi(w), \quad (\text{since } \Phi(w) \geq 0)
\]

Since \( \frac{\lambda_n}{\sqrt{n}} \rightarrow 0 \), we can then conclude by Slutsky’s theorem that (17) holds.

Hence by (16) and (17),

\[
\lambda_n \left( \Phi(c \circ |w^* + \frac{u}{\sqrt{n}}|) - \Phi(c \circ |w^*|) \right) \overset{P}{\rightarrow} \begin{cases} 0 & \text{if } u_{j^*} = 0 \\
\infty & \text{Otherwise} \end{cases}
\]  

(18)

By CLT, \( \sqrt{n \lambda_n} \overset{d}{\rightarrow} W \sim N(0, \sigma^2 Q) \), it follows then that \( V_n(u) \overset{d}{\rightarrow} V(u) \), where

\[
V(u) = \begin{cases} \frac{1}{2} u_J^T Q_J J u_J - W_J u_J & \text{if } u_{j^*} = 0 \\
\infty & \text{Otherwise} \end{cases}
\]

\( V_n \) is convex and the unique minimum of \( V \) is \( u_J = Q_J^{-1} W_J, u_{j^*} = 0 \), hence by epi-convergence results [c.f., [38]]

\[
\hat{u}_J \overset{d}{\rightarrow} Q_J^{-1} W_J \sim N(0, \sigma^2 Q_J), \quad \hat{u}_{j^*} \overset{d}{\rightarrow} 0.
\]  

(19)

Convex relaxations of combinatorial penalties.
Since $\hat{w} = \sqrt{n}(\hat{w} - w^*)$, then it follows from (19) that
\[ \hat{w}_j \overset{P}{\to} w^*_j, \quad \hat{w} \overset{P}{\to} 0 \] (20)
Hence, $P(\text{supp}(\hat{w}) \supseteq J) \to 1$ and it is sufficient to show that $P(\text{supp}(\hat{w}) \subseteq J) \to 1$ to complete the proof.

For that denote $\hat{J} = \text{supp}(\hat{w})$ and let’s consider the event $\hat{J} \setminus J \neq \emptyset$. By optimality conditions, we know that
\[ -X^T_{\hat{J} \setminus J}(X\hat{w} - y) \in \lambda_n[\partial \Phi(c \circ \cdot)(\hat{w})]_{\hat{J} \setminus J} \]

Note, that $-\frac{X^T_{\hat{J} \setminus J}(X\hat{w} - y)}{\sqrt{n}} = \frac{X^T_{\hat{J} \setminus J}X(\hat{w} - w^*)}{\sqrt{n}} - \frac{X^T_{\hat{J} \setminus J}x}{\sqrt{n}}$. By CLT, $\frac{X^T_{\hat{J} \setminus J}x}{\sqrt{n}} \overset{d}{\to} W \sim \mathcal{N}(0, \sigma^2 Q_{\hat{J} \setminus J, \hat{J} \setminus J})$ and by (20)
\[ \hat{w} - w^* \overset{P}{\to} 0 \text{ then } -\frac{X^T_{\hat{J} \setminus J}(X\hat{w} - y)}{\sqrt{n}} = O_p(1). \]

On the other hand, $\frac{X^T_{\hat{J} \setminus J}X(\hat{w} - w^*)}{\sqrt{n}} \overset{P}{\to} 0$, hence $\frac{X^T_{\hat{J} \setminus J}X(\hat{w} - w^*)}{\sqrt{n}} \to \infty$, $\forall u \in \partial \Phi(c \circ \cdot)(\hat{w})$, since $c^{-1}_{\hat{J} \setminus J}v_{\hat{J} \setminus J} = O_p(1)^{-1}$. To see this, let $w^*_j = \hat{w}_j$ and 0 elsewhere. Note that by definition of the subdifferential and the stability assumption on $J$, there must exists $M_J > 0$ s.t.
\[ \Phi(c \circ w^*) \geq \Phi(c \circ \hat{w}) + (v_{\hat{J} \setminus J}, -\hat{w}_{\hat{J} \setminus J}) \]
\[ \geq \Phi(c \circ w^*) + M_J\|[c_{\hat{J} \setminus J} \circ \hat{w}_{\hat{J} \setminus J}]\|_\infty - \|[c_{\hat{J} \setminus J} \circ \hat{w}_{\hat{J} \setminus J}]\|_1 \]
\[ \Rightarrow \frac{X^T_{\hat{J} \setminus J}X(\hat{w} - w^*)}{\sqrt{n}} \overset{P}{\to} 0 \]
We deduce then $P(\text{supp}(\hat{w}) \subseteq J) = 1 - P(\hat{J} \setminus J \neq \emptyset) = 1 - P(\text{optimality condition holds}) \to 1$.

### 7.4 Discrete stability (Proof of Proposition and relation to weak submodularity)

**Proposition 2.** If $F$ is a finite-valued monotone function, $F$ is $\rho$-submodular iff discrete weak stability is equivalent to strong stability.

**Proof.** If $F$ is $\rho$-submodular and $J$ is weakly stable, then $\forall A \subseteq J, \forall i \in J^c, 0 < \rho[F(J \cup \{i\}) - F(J)] \leq F(J \cup \{i\}) - F(J)$, i.e., $J$ is strongly stable w.r.t. $F$. If $F$ is such that any weakly stable set is also strongly stable, then if $F$ is not $\rho$-submodular, then $\forall \rho \in (0, 1]$ there must exists a set $B \subseteq V$, s.t., $3A \subseteq B, i \in B^c, s.t., \rho[F(B \cup \{i\}) - F(B)] > F(A \cup \{i\}) - F(A) \geq 0$. Hence, $F(B \cup \{i\}) - F(B) > 0$, i.e., $B$ is weakly stable and thus it is also strongly stable and we must have $F(A \cup \{i\}) - F(A) > 0$. Choosing then in particular, $\rho = \min_{B \subseteq V} \min_{A \subseteq B, i \in B^c} \frac{F(A \cup \{i\}) - F(A)}{F(B \cup \{i\}) - F(B)} \in (0, 1]$, leads to a contradiction; $\min_{A \subseteq B, i \in B^c} F(A \cup \{i\}) - F(A) \geq \rho[F(B \cup \{i\}) - F(B)] > F(A \cup \{i\}) - F(A)$.

We show that $\rho$-submodularity is a stronger condition than weak submodularity. First, we recall the definition of weak submodular functions.

**Definition 7 (Weak Submodularity (c.f., [7, 11])).** A function $F$ is weakly submodular if $\forall S, L, S \cap L = \emptyset, F(L \cup S) - F(L) > 0$,
\[ \gamma_{S,L} = \frac{\sum_{i \in S} F(L \cup \{i\}) - F(L)}{F(L \cup S) - F(L)} > 0 \]

**Proposition 8.** If $F$ is $\rho$-submodular then $F$ is weakly submodular. But the converse is not true.

**Proof.** If $F$ is $\rho$-submodular then $\forall S, L, S \cap L = \emptyset, F(L \cup S) - F(L) > 0$, let $S = \{i_1, i_2, \cdots, i_r\}$
\[ F(L \cup S) - F(L) = \sum_{k=1}^{r} F(L \cup \{i_1, \cdots, i_k\}) - F(L \cup \{i_1, \cdots, i_{k-1}\}) \]
\[ \leq \sum_{k=1}^{r} \frac{1}{\rho} (F(L \cup \{i_k\}) - F(L)) \]
\[ \Rightarrow \gamma_{S,T} = \rho > 0. \]
We show that the converse is not true by giving a counter-example: Consider the function defined on \( V = \{1, 2, 3\} \), where \( F((i)) = 1, \forall i, F((1, 2)) = 1, F((2, 3)) = 2, F((1, 3)) = 2, F((1, 2, 3)) = 3 \). Then note that this function is weakly submodular. We only need to consider sets \(|S| \geq 2\), since otherwise \( \gamma_{S,T} > 0 \) holds trivially. Accordingly, we also only need to consider \( L \) which is the empty set or a singleton. In both cases \( \gamma_{S,T} > 0 \). However, this \( F \) is not \( \rho \)-submodular, since \( F(1, 2) - F(1) = 0 < \rho(F(1, 2, 3) - F(1, 3)) = \rho \) for any \( \rho > 0 \).

\[ \Box \]

### 7.5 Relation between discrete and continuous stability (Proof of Proposition 3 and Corollary 3)

First, we present a useful simple lemma, which provides an equivalent definition of decomposability for monotone function.

**Lemma 7.** Given \( w \in \mathbb{R}^d, J \subseteq J, \supp(w) = J \), if \( \Phi \) is a monotone function, then \( \Phi \) is decomposable at \( w \) w.r.t \( J \) iff \( \exists M_j > 0, \forall \delta > 0, i \in J^c, s.t. \)

\[ \Phi(w + \delta \mathbf{1}_i) \geq \Phi(w) + M_j \delta. \]

**Proof.** By definition \[2\], \( \exists M_j > 0, \forall \Delta \in \mathbb{R}^d, \supp(\Delta) \subseteq J^c \),

\[ \Phi(w + \Delta) \geq \Phi(w) + M_j \| \Delta \|_\infty. \]

in particular this must hold for \( \Delta = \delta \mathbf{1}_i \). On the other hand, if the inequality hold for all \( \delta \mathbf{1}_i \), then given any \( \Delta \) s.t. \( \supp(\Delta) \subseteq J^c \) let \( i_{\text{max}} \) be the index where \( \Delta_{i_{\text{max}}} = \| \Delta \|_\infty \) and let \( \delta = \| \Delta \|_\infty \), then

\[ \Phi(w + \Delta) \geq \Phi(w + \delta i_{\text{max}}) \geq \Phi(w) + M_j \delta = \Phi(w) + M_j \| \Delta \|_\infty. \]

\[ \Box \]

**Proposition 3.** Given any monotone set function \( F \), all sets \( J \subseteq V \) strongly stable w.r.t \( F \) are also strongly stable w.r.t \( \Omega_p \) and \( \Theta_p \).

**Proof.** We make use of the variational form \( [1] \). Given a set \( J \) stable w.r.t \( F \) and \( \supp(w) \subseteq J \), let \( \kappa^* \in \arg \max_{\kappa \in \mathbb{R}_+^d} \left\{ \sum_{i \in J} \kappa_i^{1/q} |w_i| : \kappa(A) \leq F(A), \forall A \subseteq V \right\} \), then \( \Omega_p(w) = |w_j|^p (\kappa_j^*)^{1/q} \). Note that \( \forall A \subseteq J, F(A) > F(A) \), by definition \( [3] \). Hence, \( \forall i \in J^c \), we can define \( \kappa' \in \mathbb{R}_+^d \) s.t., \( \kappa_i' = \kappa_j' = \kappa_i + \kappa_j < \kappa_j \), \( \kappa_i' = \min_{A \subseteq J} F(A) - F(A) > 0 \). Note that \( \kappa' \) is feasible, since \( \forall A \subseteq J, \kappa'(A) = \kappa^*(A) \leq F(A) \) and \( \kappa'(A) = \kappa^*(A) \leq F(A) + F(A) = F(A) \). For any other set \( \kappa'(A) = \kappa'(A \cap (J + i)) \leq F(A \cap (J + i)) \leq F(A) \), by monotonicity. It follows then that \( \Omega_p(w + \delta \mathbf{1}_i) = \max_{\kappa \in \mathbb{R}_+^d} \left\{ \sum_{i \in J \cup i} \kappa_i^{1/q} |w_i| : \kappa(A) < F(A), \forall A \subseteq V \right\} \geq |w_j|^p (\kappa_j^*)^{1/q} + \delta (\kappa_j^*)^{1/q} \geq \Omega_p(w) + \delta M \), with \( M = (\kappa_j^*)^{1/q} \). The proposition then follows by lemma \( [7] \).

Similarly, the proof for \( \Theta_p \) follows in a similar fashion. We make use of the variational form \( [14] \). Given a set \( J \) stable w.r.t \( F \) and \( \supp(w) \subseteq J \), first note that this implicity implies that \( F(J) < +\infty \) and hence \( \Theta_p(w) < +\infty \). Let \( \kappa^* \in \arg \max_{\kappa \in \mathbb{R}_+^d} \left\{ \sum_{j=1}^d \psi_j(\kappa_j, w_j) + \min_{S \subseteq J} F(S) - \kappa(S) \right\} \). Note that \( \forall S \subseteq J, \forall i \in J^c, F(S \cup i) > F(S), \) by definition \( [3] \). Hence, \( \forall i \in J^c, \) we can define \( \kappa' \in \mathbb{R}_+^d \) s.t., \( \kappa_i' = \kappa_j' = \kappa_j \), \( \delta_i = \min_{S \subseteq J} F(S \cup i) - F(S) > 0 \). Note that \( \forall S \subseteq J, F(S) - \kappa^*(S) = F(S) - \kappa^*(S) \geq F(S^*) - \kappa^*(S^*) \). For any \( \kappa'(A) = \kappa'(A \cap (J + i)) \leq F(A \cap (J + i)) \leq F(A) \), by monotonicity. It follows then that \( \Theta_p(w + \delta \mathbf{1}_i) \geq \sum_{i \in J} \psi_i(\kappa_j, w_j) + (\kappa_j^{1/\delta})^{1/\delta} + \min_{S \subseteq J} F(S) - \kappa^*(S) \geq \sum_{i \in J} \psi_i(\kappa_j, w_j) + (\kappa_j^{1/\delta})^{1/\delta} \). The proposition then follows by lemma \( [7] \).

**Proposition 4.** If \( F = F_\infty \) and \( J \) is strongly stable w.r.t \( \Omega_\infty \), then \( J \) is strongly stable w.r.t \( F \). Similarly, for any monotone \( F \), if \( J \) is strongly stable w.r.t \( \Theta_\infty \), then \( J \) is strongly stable w.r.t \( F \).

**Proof.** \( F(A + i) = \Omega_\infty(\mathbf{1}_A + \mathbf{1}_i) = \Theta_\infty(\mathbf{1}_A + \mathbf{1}_i) > \Omega_\infty(\mathbf{1}_A) = \Theta_\infty(\mathbf{1}_A) = F(A), \forall A \subseteq J \).

**Corollary 3.** If \( F \) is monotone submodular and \( J \) is weakly stable w.r.t \( \Omega_\infty = \Theta_\infty \), then \( J \) is weakly stable w.r.t \( F \).

**Proof.** If \( F \) is a monotone submodular function, then \( \Omega_\infty(w) = \Theta_\infty(w) = f_L(|w|) \). If \( J \) is not weakly stable w.r.t \( F \), then \( \exists i \in J^c \) s.t., \( F(J \cup \{i\}) = F(J) \). Thus, given any \( w, \supp(w) = J \), choosing \( 0 < \delta < \min_{i \in J} |w_i| \), result in \( f_L(|w| + \delta \mathbf{1}_i) = f_L(|w|) \), which contradicts the weak stability of \( J \) w.r.t \( \Omega_\infty = \Theta_\infty \).

\[ \Box \]
