

# **From Probability Graphical Models to Dynamic Networks**

**—  
A Bayesian perspective on Smooth Best Estimate of Trajectory with  
applications in Geodetic Engineering**

**Jospin L.V., Layahe J., Skaloud J.  
ESO – CRYOS – ENAC - EPFL**

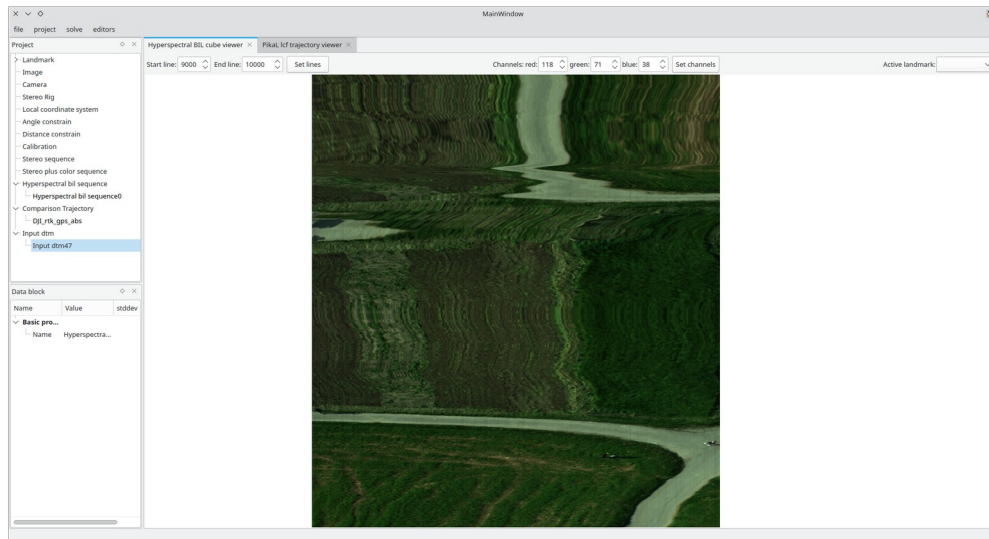

# A quick word about myself

- Background in computer vision, software engineering and statistical modelling.
- Working at EPFL, in the Environnement Sensing Observatory (ESO), a part of the CRYOS Lab in the ENAC faculty.
- Working on modelling new sensors in the factor graph optimization toolkit developed by ESO : Dynamic Network.

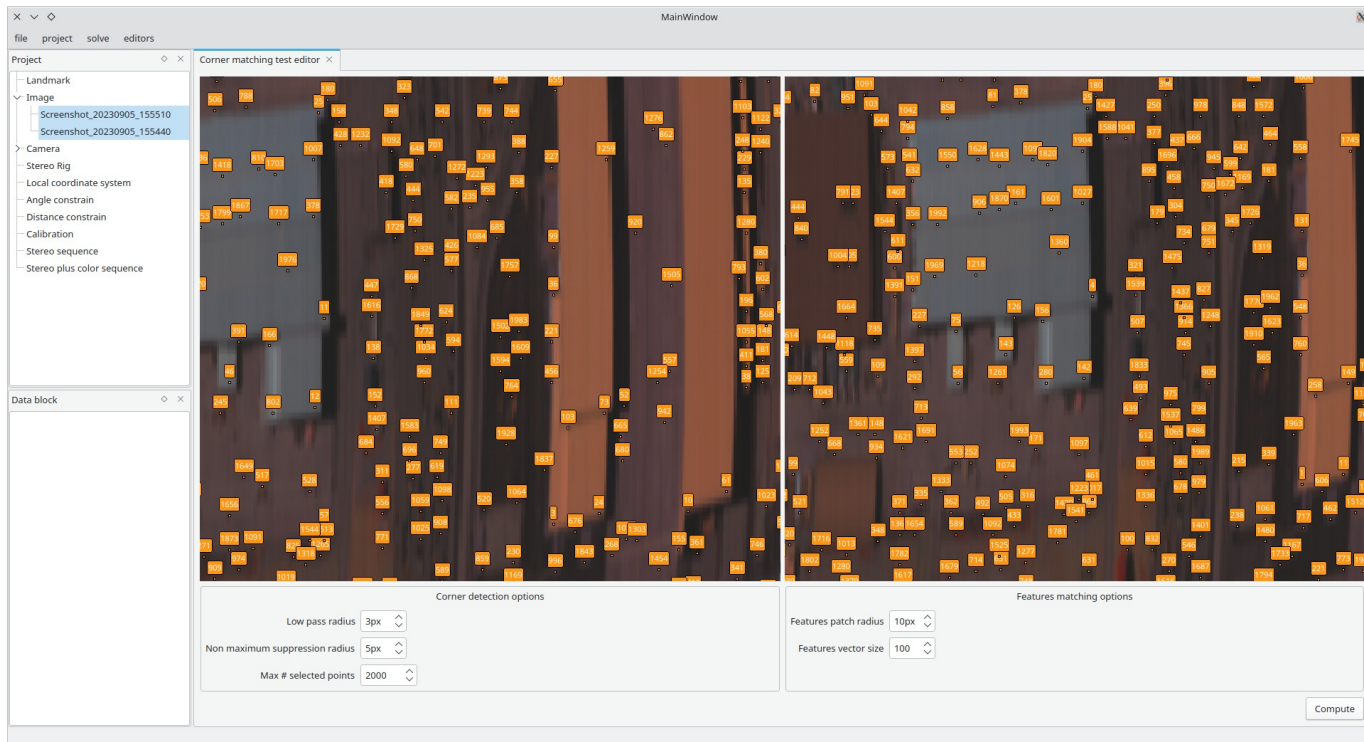

# Table of content

- Motivation – flying a lightweight hyperspectral camera with a drone
- Bayesian vs Frequentist, what is the difference
- Bayesian modelling – probability distributions as graphs
- A practical example – modelling a push-broom hyperspectral camera mapping campaign
- Some preliminary results

# Challenges in mapping with lightweight hyperspectral sensors

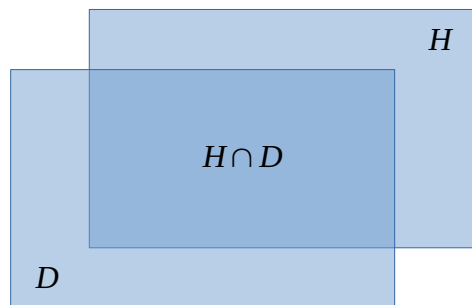

# Hundreds of tie points, no redundancy

# Bayesian vs Frequentist

$$P(H|D) = \frac{P(D|H)P(H)}{P(D)} = \frac{P(D|H)P(H)}{\int P(D|H)P(H)dH} = \frac{P(D,H)}{P(D)}$$

Frequentist interpretation  
(set and measure theory)

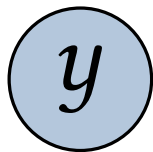

Bayesian interpretation  
(information theory)

$H$  Initial information about hypothesis

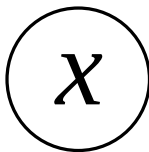

$D$  Data measurements

$H|D$  Refined knowledge with new evidences

# Bayesian modelling – Probabilistic Graphical Models (PGM)

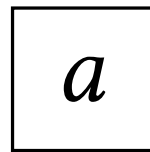

Observation

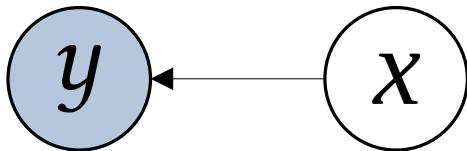

Latent (unobserved)  
variables

Function

Parameter

Conditional dependence of  
y on x in the prior

Conditional dependence of y  
on x and x on y in the prior

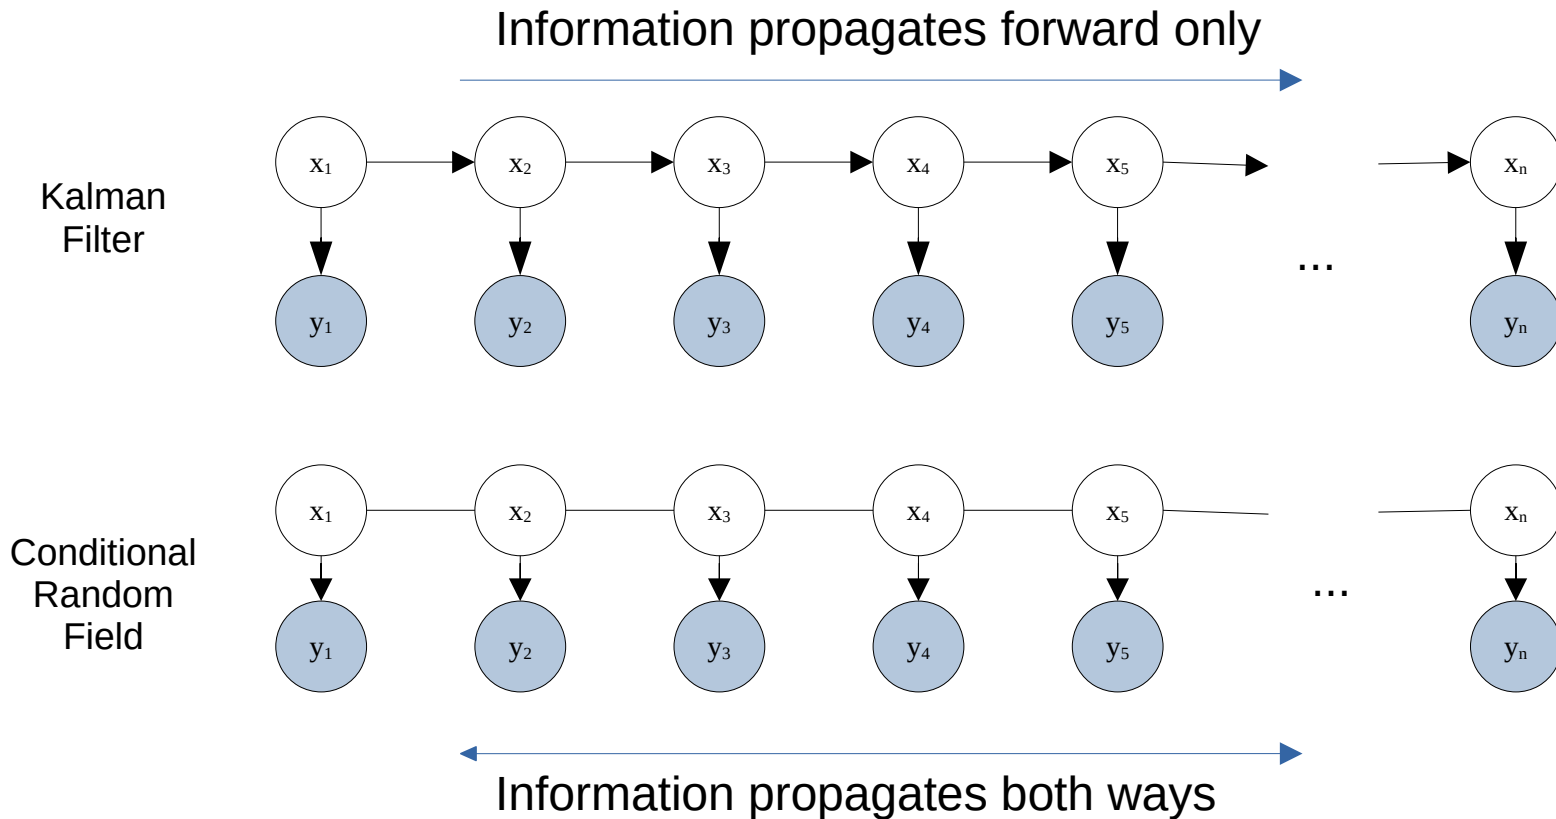

Directed PGM:

$$p(v_1, \dots, v_n) = \prod_{i=1}^n p(v_i | \text{parents}(v_i))$$

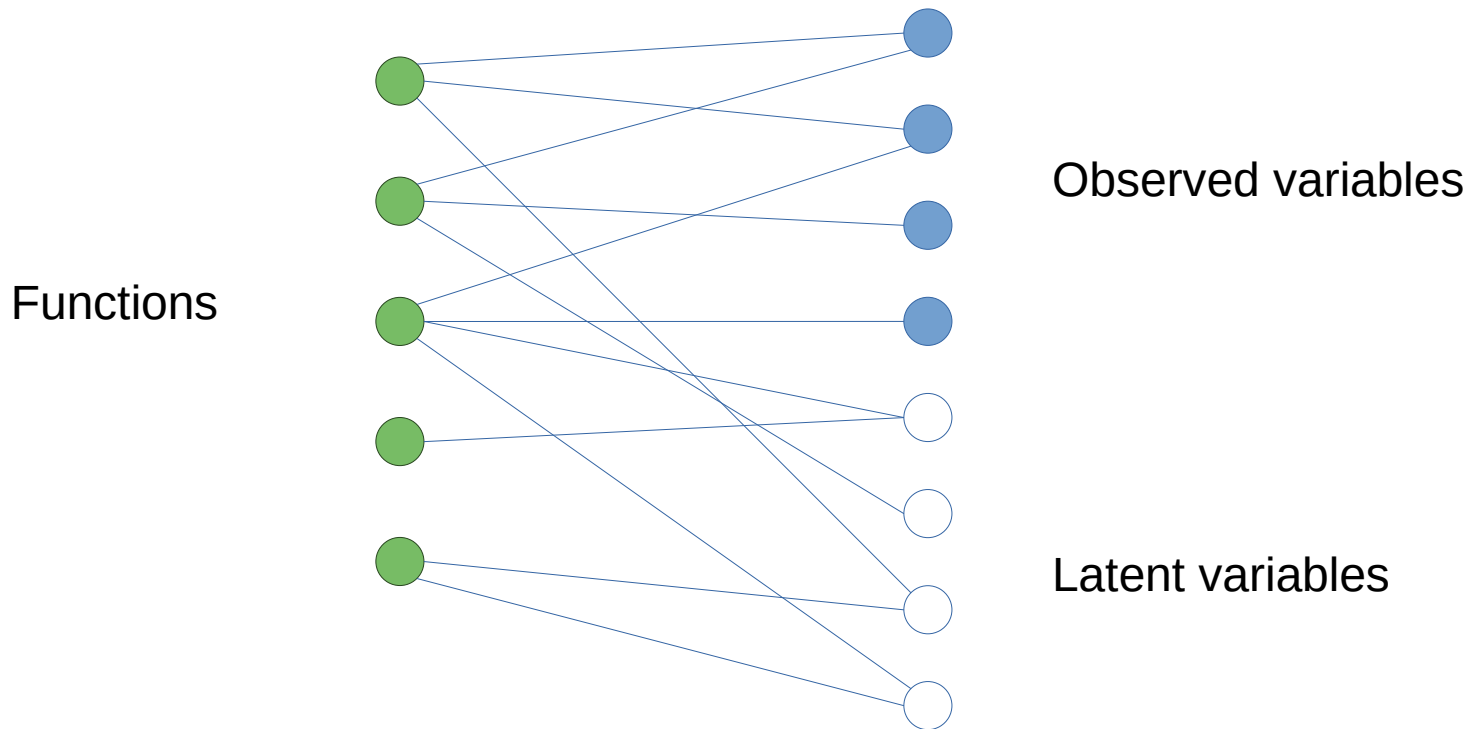

Undirected PGM:

$$p(v_1, \dots, v_n) = \prod_{i=1}^n f(v_i, \text{connected}(v_i))$$

# The Kalman Filter vs Conditional Random Field

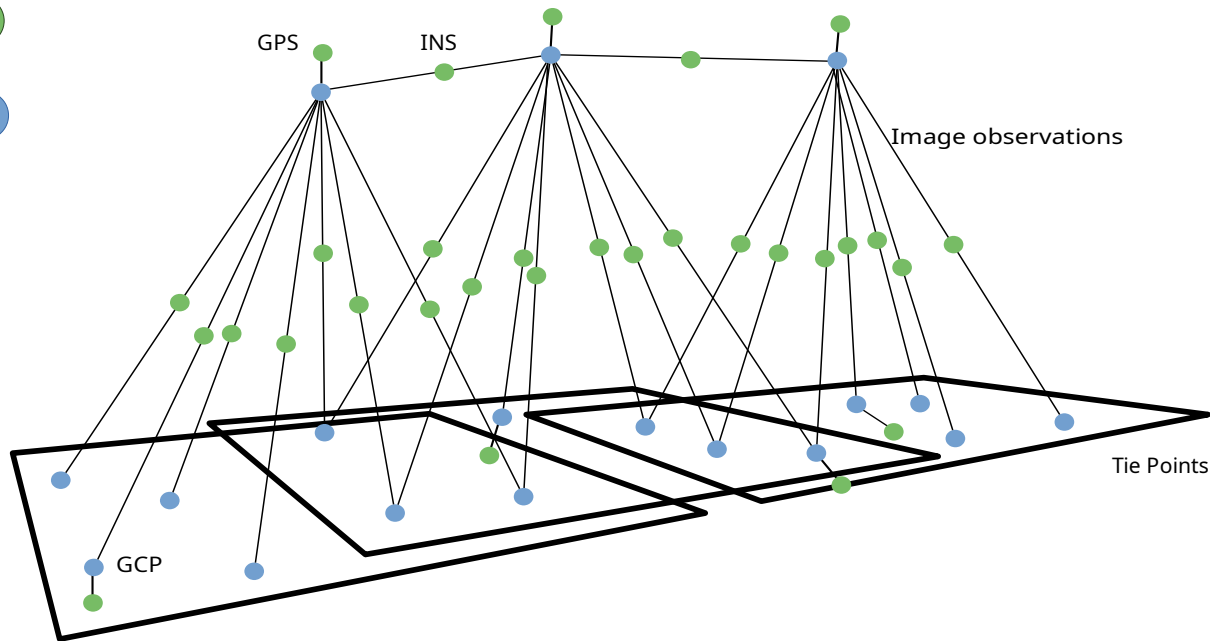

# Factor graphs – modelling joint distributions

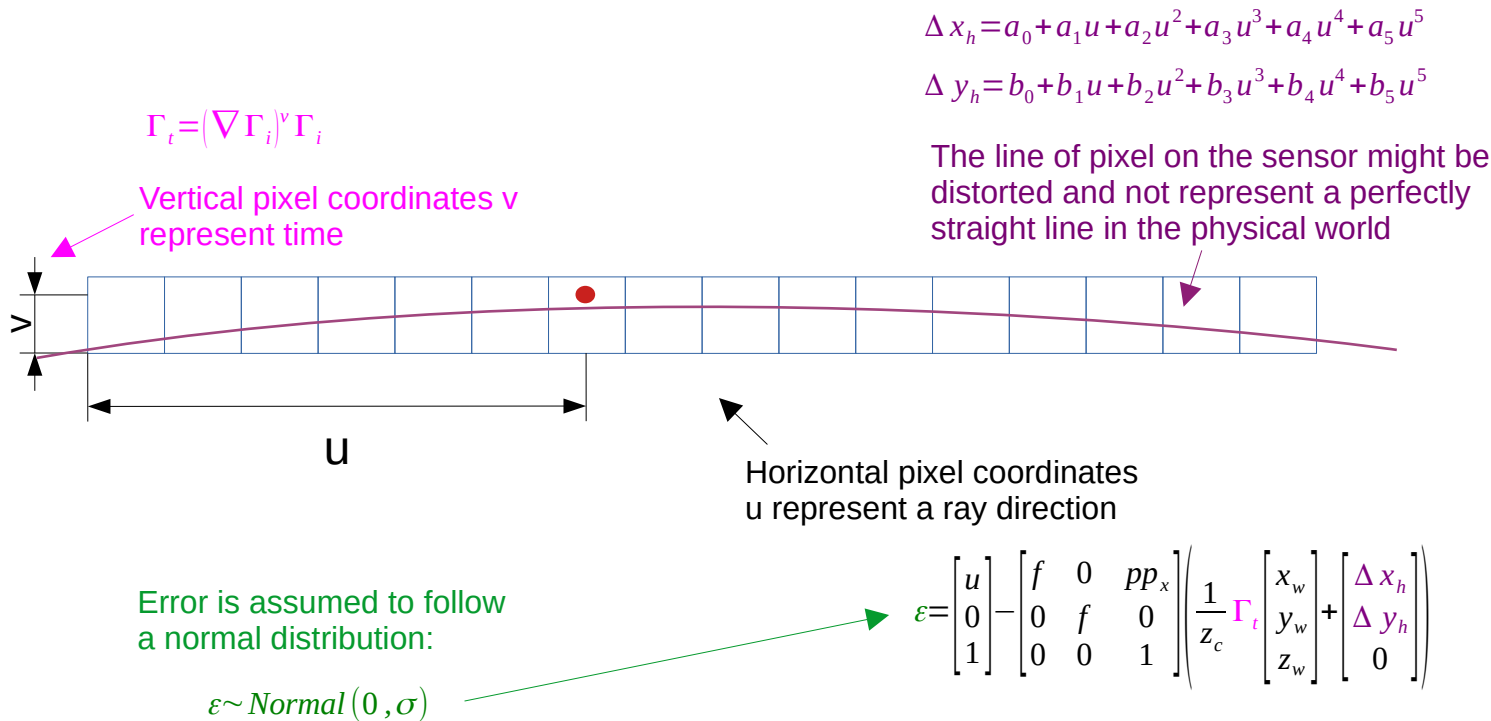

# Modelling a factor graph – Bundle adjustment example

Functions ●

Variables ●

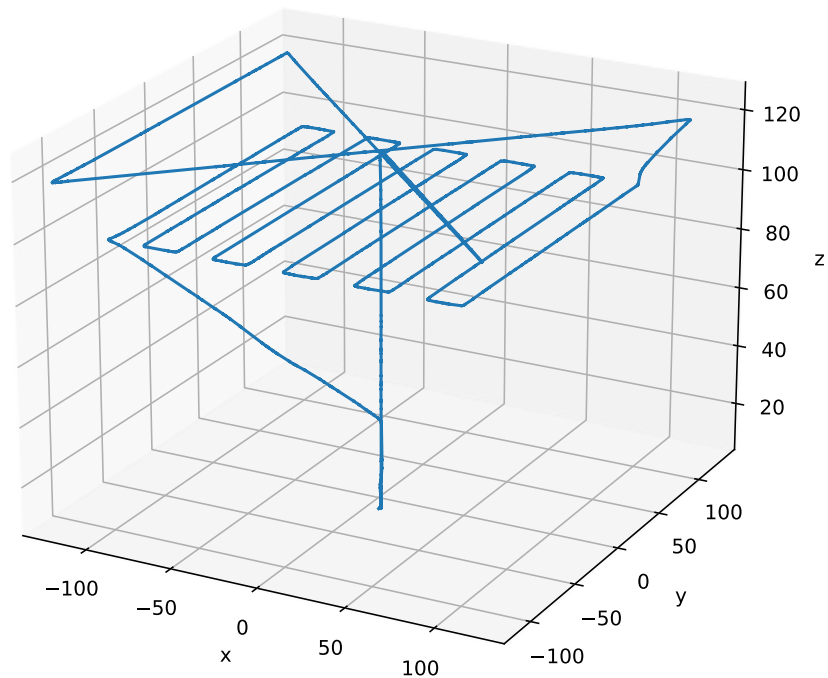

# Modelling a push-broom hyperspectral camera

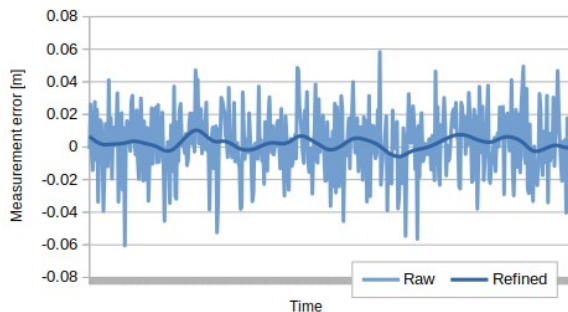

# Simulated data for experiments

- Simulate a basic flight
- Based on quadcopter dynamic
- Basic normal noise models for sensors (GPS/INS)
- Simulated 1000 tie points distribution on random terrain
- Factor graph built with normal position prior based on GPS, normal speed priors based on INS and tie points observations

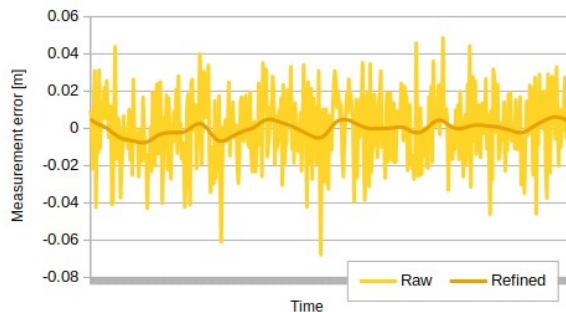

# Some preliminary results

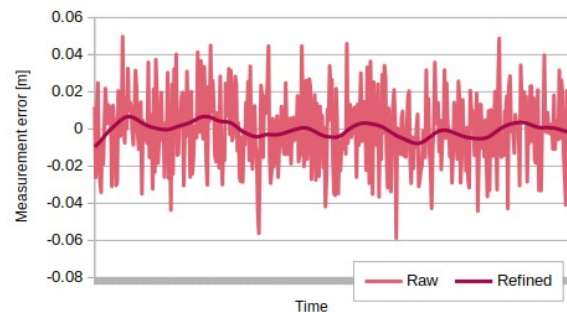

Position error X

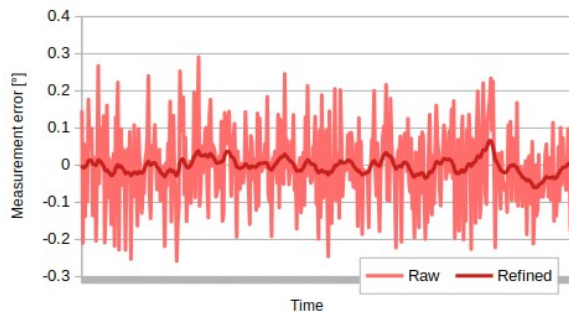

Position error Y

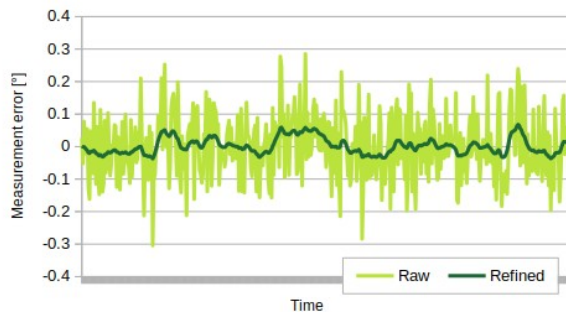

Position error Z

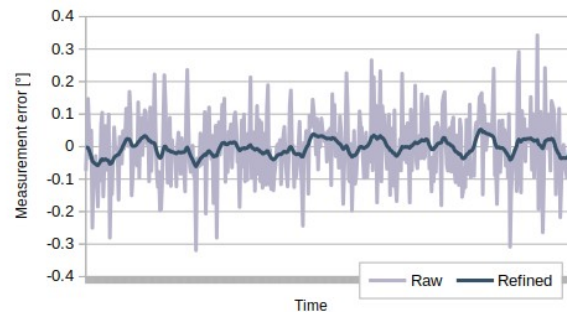

Orientation error X

Orientation error Y

Orientation error Z

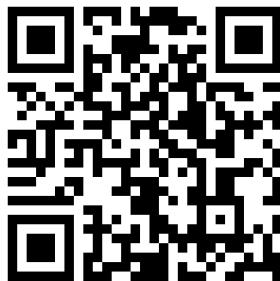

# Next steps

- Initial testing on simulated data supported the stability and accuracy of the proposed approach.
- Models hyperparameters and additional priors needs to be fine-tuned on real data.
- A flight campaign, with drone, helicopter and plane flights, is scheduled for 2024.
- We are open for collaborations if the project is relevant for your own research !

# Trying out Dynamic Network (DN)

- DN is our implementation of factor graph optimization, based on the library ROAMFREE, for geodetic engineering applications (so far for photogrammetry and lidar flights optimization, hyperspectral coming soon).
- Publicly available at [https://odyn.epfl.ch/app\\_direct/odyn/](https://odyn.epfl.ch/app_direct/odyn/)

**Thank you**
