Dynamically Orthogonal Approximation for
Stochastic Differential Equations

Abstract

In this paper, we set the mathematical foundations of the Dynamical Low Rank Approximation (DLRA) method for high-dimensional stochastic differential equations. DLRA aims at approximating the solution as a linear combination of a small number of basis vectors with random coefficients (low rank format) with the peculiarity that both the basis vectors and the random coefficients vary in time.

While the formulation and properties of DLRA are now well understood for random/parametric equations, the same cannot be said for SDEs and this work aims to fill this gap. We start by rigorously formulating a Dynamically Orthogonal (DO) approximation (an instance of DLRA successfully used in applications) for SDEs, which we then generalize to define a parametrization independent DLRA for SDEs. We show local well-posedness of the DO equations and their equivalence with the DLRA formulation. We also characterize the explosion time of the DO solution by a loss of linear independence of the random coefficients defining the solution expansion and give sufficient conditions for global existence.

1 Introduction

This paper is concerned with the theoretical foundation of dynamical low-rank methods for stochastic differential equations (SDEs). Low-rank methods aim to approximate solutions of high-dimensional differential equations in a well chosen low dimensional subspace. Such methods are widely used in computational science and industrial applications \cite{2, 22, 30, 36}. Our focus here is on low-rank methods for high-dimensional SDEs, which is a case of primary interest, for instance in finance \cite{32, 31}, or in various applications such as biology \cite{1} or machine learning \cite{28} where SDEs often appear as discretizations of Stochastic Partial Differential Equations (SPDEs).

Among such low-rank methods, of particular interest in this paper is the Dynamically Orthogonal (DO) approximation \cite{33}, which is known to be an equivalent formulation of the so-called Dynamical Low Rank Approximation (DLRA)\cite{18} when applied to random PDEs (see \cite{27, 24}). Given a high-dimensional matrix differential equation, the main idea of DLRA is to constrain the dynamics to the manifold of matrices of fixed (small) rank; this corresponds to projecting the right-hand side, defining the time derivative of the studied dynamics, onto the tangent space of the low-rank manifold at every instant of time. This procedure requires the differentiability in time of the solution, needed to recover the system of equations that describe the DLRA.

Concerning specifically the DO method, this strategy approximates random or stochastic time-dependent equations by using a sum of a small number of products between spatial and
stochastic basis functions, thus leading to a low-rank approximation with explicit parametrization of the low-rank factors. This implies that, unlike DLRA, the DO strategy is parametrization dependent. A crucial distinction from classical reduced order models is that, in the DO framework, both the spatial and stochastic basis functions depend on time; see for example [27, 9] for more details. The DO/DLRA methodology has been successfully applied in several fields; various promising computational results are available for applications to random partial differential equations (RPDEs) [8, 6, 7, 9, 27, 25, 26, 15, 33], to SDEs [33, 34, 35, 38], and to measure-valued equations associated with SDEs in [33, 4].

The DO approximation is given by the solution of a system of equations, which provide the evolution of the deterministic and stochastic basis functions. This system is however highly nonlinear, even if the original dynamics was linear. In addition, its well-posedness is not obvious due to the presence of the inverse of a Gramian, which is not guaranteed to exist at all times. Moreover, in the specific case of SDEs, the DO solution depends on the law of the whole process at every instant of time. These features make the well-posedness study challenging and non-standard, questioning also whether the existence of solutions is global or only local and, in the latter case, what happens at the solution at the explosion time. Besides being of interest per se, a well-posedness study of the DO equations is also important to derive consistent and stable time discretization schemes, which are eventually needed to apply these techniques in real-life problems.

For RPDEs, theoretical results on the existence and uniqueness of the solution of the DO equations [14], as well as stability and error estimates of time discretization schemes [15, 27, 40] are available. An existence and uniqueness result is also available for the DLR approximation of two-dimensional deterministic PDEs [3], where the sum involves products of basis functions for the different spatial variables. In contrast, for SDEs well-posedness results remain largely unexplored. This lack of theory for SDEs is unfortunate, since DO approximations are very appealing and have been widely used in several problems modeled by SDEs (see e.g. [33, 34, 35, 38]). This paper aims at filling this gap between application and theory by:

- (Re-)deriving the DO equations for SDEs. We also derive the corresponding parametrization independent DLRA equation for SDEs.
- Showing the equivalence between DO approximation and DLRA. By exploiting this equivalence, we show that the DO equations and the DLRA equation are well-posed.
- Characterising the finite explosion time in terms of the linear independence of the stochastic DO basis.
- Discussing the extension of DLRA beyond the explosion time. We also provide a sufficient condition under which the DO/DLRA solution exists globally.

More precisely, we start by revisiting the DO equations for SDEs, which were originally derived in [33] relying on the formal assumption that the DO solution is time differentiable, a property that SDE solutions do not possess. Deriving DO equations without using the time derivatives is a fundamental challenge, since the essence of the usual DLR methodology consists in projecting the time derivative onto the tangent space of the low-rank manifold. We overcome this challenge by pushing the differentiability to the spatial basis, while the stochastic basis remains non-differentiable. It turns out that this alternative approach leads to the same DO equations as in [33], supporting their validity as a correct dynamical low-rank approximation.

In the DLR literature [18, 16], it is well known by now that, when applied to RPDEs, the DO formulation is just a specific parametrisation of the DLR, the parameters being the deterministic and stochastic time-dependent bases defining the DO solution [27, 14]. In this paper, we derive an analogous result for SDEs. In particular, starting from the DO equations, we derive a parameter independent low-rank approximation which we name DLRA for SDEs, and show its equivalence with the DO formulation. The main result of this work is to prove local existence and uniqueness to both DO and DLRA equations. As a part of our existence result, we give a characterisation of the interval \([0, T_e]\) on which the solution exists. More specifically, we
show that, if the explosion time $T_e$ is finite, then the stochastic DO basis must become linearly dependent at $T_e$.

Although the characterisation of the explosion time provides us a valuable insight into the DO solution, it is not satisfactory from the practical point of view; if the true solution still exists at $T_e$ and beyond, we expect any sensible approximation to exist as well. Under some mild integrability condition on the initial datum, we show that, while the DO solution ceases to exist at the explosion time $T_e$, the DLRA can be continuously extended up to $T_e$ and beyond. Thus, our findings offer insights on how to continue a DO approximation beyond the explosion time $T_e$. As a final result, we show that a sufficient condition for global existence of a DO solution (i.e. $T_e = +\infty$) is that the noise in the SDE is non-degenerate.

The rest of the paper is organised as follows. Section 2 introduces the DO equations, together with theoretical justifications for why they are sensible. Furthermore, it introduces a DLRA formulation that does not depend on the parametrisation. Section 3 concerns the local well-posedness of the DO equations, where we also show the continuity of the solution with respect to the initial data. In Section 4, we study the behaviour of the solution up to and beyond the explosion time $T_e$. In Section 5 we draw some conclusions and perspectives.

2 The DO equations

Let $(\Omega, \mathcal{F}, \mathbb{P}; (\mathcal{F}_t)_{t \geq 0})$ be a filtered complete probability space with the usual conditions; see for example [37, Remark 6.24]. Consider the stochastic differential equation (SDE)

$$X^{\text{true}}(t) = X^{\text{true}}_0 + \int_0^t a(s, X^{\text{true}}(s)) \, ds + \int_0^t b(s, X^{\text{true}}(s)) \, dW_s, \quad (2.1)$$

where $W_t = (W_t^1, \ldots, W_t^m)^T$ is a standard $m$-dimensional $(\mathcal{F}_t)$-Brownian motion. Here, we used the notation $X^{\text{true}}(t, \omega) = (X^{\text{true}}_1(t, \omega), \ldots, X^{\text{true}}_d(t, \omega))^T \in \mathbb{R}^d$ for $t \geq 0$ and $\omega \in \Omega$. Let $| \cdot |$ and $\| \cdot \|_F$ denote the Euclidean norm and the Frobenius norm, respectively. We work with the following assumptions.

**Assumption 1.** The drift coefficient $a: [0, \infty) \times \mathbb{R}^d \to \mathbb{R}^d$ and the diffusion coefficient $b: [0, \infty) \times \mathbb{R}^d \to \mathbb{R}^{d \times m}$ are Lipschitz continuous with respect to the second variable, uniformly in time:

$$\begin{align*}
|a(s, x) - a(s, y)| &\leq C_{\text{Lip}} |x - y|, \\
\|b(s, x) - b(s, y)\|_F &\leq C_{\text{Lip}} |x - y|,
\end{align*} \quad (2.2)$$

for some constant $C_{\text{Lip}} > 0$. Moreover, $a$ and $b$ are jointly measurable.

**Assumption 2.** The drift $a$ and the diffusion $b$ satisfy the following linear-growth bound condition

$$|a(s, x)|^2 + \|b(s, x)\|_F^2 \leq C_{\text{Lip}} (1 + |x|^2) \quad (2.3)$$

for some constant $C_{\text{Lip}} > 0$.

Furthermore, we assume that the initial condition $X^{\text{true}}_0$ in (2.1) satisfies the following:

**Assumption 3.**

$$X^{\text{true}}_0 \text{ is } \mathcal{F}_0\text{-measurable and satisfies } \mathbb{E}[|X^{\text{true}}_0|^2] < +\infty. \quad (2.4)$$

Under these assumptions, equation (2.1) has a unique strong solution; see for example [37, Theorem 21.13].

Let us consider a positive integer $R$ such that $R \leq d$. To numerically approximate (2.1), in this work we consider dynamically orthogonal approximations of the form

$$X^{\text{true}} \approx X := U^T \bar{Y} := \sum_{j=1}^R U_j Y_j \in \mathbb{R}^d, \quad (2.5)$$
where $U = (U_t)_{t \in [0,T]}$ is a deterministic absolutely continuous matrix-valued function that gives an orthogonal matrix in $\mathbb{R}^{R \times d}$ for all $t$, whereas $Y = (Y_t)_{t \in [0,T]}$ is an Itô process with values in $\mathbb{R}^R$ with linearly independent components for all $t$. It is worth pointing out that for all $t \in [0,T]$ and $\omega \in \Omega$, the approximate process $X_t(\omega)$ belongs to an $R$ dimensional vector space spanned by the rows of $U_1^R, \ldots, U_t^R$ of $U_t$, whereas each component of $X_t^j, j = 1, \ldots, d$, belongs to span$(Y_1^j, \ldots, Y_t^j)$.

Approximations of the form (2.5) for SDEs have been considered already in [33], where the following evolution equations, hereafter called DO equations, were derived for the factors $(U, Y)$ by formal calculations, treating the process $Y_t$ as differentiable:

$$C \dot{Y}_t, \dot{U}_t = E[Y_ta(t, U_t^\top Y_t^\top)](I_{d \times d} - P_{U_t}^{\text{row}}),$$

(2.6)

$$dY_t = U_t a(t, U_t^\top Y_t)\, dt + U_t b(t, U_t^\top Y_t)\, dW_t.$$  

(2.7)

Here, we let $C \dot{Y}_t := E[Y_t^\top Y_t^\top]$ whereas $P_{U_t}^{\text{row}} \in \mathbb{R}^{d \times d}$ denotes the projection-matrix onto the row space spanned by the rows of $U_t$; when $U_t$ has orthonormal rows, one has $P_{U_t}^{\text{row}} = U_t^\top U_t$.

In Section 2.1, we will give a rigorous justification for (2.6) and (2.7).

Having stated these equations, we now define the strong DO solution and DO approximation for an SDE problem of the type (2.1).

**Definition 2.1 (Strong DO solution).** A function $(U, Y) : [0, T] \to \mathbb{R}^{R \times d} \times L^2(\Omega; \mathbb{R}^R)$ is called a **strong DO solution** for (2.1) if the following conditions are satisfied:

1. $(U_0, Y_0) = (\varphi, \xi)$, for some $\varphi \in \mathbb{R}^{R \times d}$ matrix with orthonormal rows and $\xi \in L^2(\Omega; \mathbb{R}^R)$ with linearly independent components;

2. the curve $t \mapsto U_t \in \mathbb{R}^{R \times d}$ is absolutely continuous on $[0, T]$. Moreover, $U_t$ has orthonormal rows for all $t \in [0, T]$, and $U_t U_t^\top = 0$ in $\mathbb{R}^{R \times R}$ for a.e. $t \in [0, T]$;

3. the curve $t \mapsto Y_t(\omega) \in \mathbb{R}^R$ has almost surely continuous paths on $[0, T]$ and it is $\mathcal{F}_t$-measurable for all $t \in [0, T]$. Moreover, for any $t \in [0, T]$ the components $Y_t^1, \ldots, Y_t^R$ are linearly independent in $L^2(\Omega)$;

4. $U$ satisfies equation (2.6) for a.e. $t \in [0, T]$ and $Y$ is a strong solution of (2.7) on $[0, T]$.

For convenience, given a DO solution $(U, Y)$ we call the product $U^\top Y$ a DO approximation.

**Definition 2.2 (DO approximation).** We call a process $X : [0, T] \to L^2(\Omega; \mathbb{R}^R)$ a **DO approximation** of (2.1) if there exists a strong DO solution $(U, Y)$ such that $X_t := U_t^\top Y_t$ for all $t \in [0, T]$.

Given a DO approximation $X$, the corresponding DO solution $(U, Y)$ is determined only up to a (process of) rotation matrix. Indeed, let $(U, Y)$ and $(\tilde{U}, \tilde{Y})$ be two strong DO solutions such that $U_t Y_t = \tilde{U}_t \tilde{Y}_t = X_t$ for all $t \geq 0$. Then the orthogonality of $U_t$ implies $\tilde{Y}_t = O_t Y_t$ with $O_t = \tilde{U}_t U_t^\top$. The matrix $O_t$ is orthogonal for every $t \in [0, T]$, but not necessarily an identity. See Section 2.3, in particular Proposition 2.9, for more details.

### 2.1 Consistency of the DO equations

In this section, we rigorously show the consistency of the DO equations (2.6) and (2.7) in the sense described hereafter. Assume that the exact solution of (2.1) is of the form $X = \sum_{j=1}^R U_j Y_j^\top$ with deterministic function $U_t = (U_1^R, \ldots, U_t^R)^\top \in \mathbb{R}^{R \times d}$ and an Itô process $Y_t(\omega) = (Y_t^1(\omega), \ldots, Y_t^R(\omega))^\top \in [L^2(\Omega)]^R$ for some $R \leq d$ that fulfill the following properties:

1. the function $[0, T] \ni t \mapsto U_t \in \mathbb{R}^{R \times d}$, $d \geq R$, is absolutely continuous on $[0, T]$ and satisfies $U_t U_t^\top = 0$ in $\mathbb{R}^{R \times R}$ for almost every $t \in [0, T]$; moreover, $U_t U_t^\top = I \in \mathbb{R}^{R \times R}$ for almost every $t \in [0, T]$, where $I$ is the identity matrix;
where $P$ and $Y$.

The DO equations (2.6)–(2.7) are posed as a system of equations for the separate factors $X$ and $Y$.

Then $(U_t, Y_t)$ must satisfy equations (2.6) and (2.7).

Indeed, since $\alpha_t$ and $\beta_t$ in (2.8) are progressively measurable, by applying Itô’s formula [10, 20] we have

$$dX_t = (dU_t^T)Y_t + U_t^T dY_t + \sum_{j=1}^R d(U_j, Y_j)(t)$$

$$= U_t^T Y_t dt + U_t^T (\alpha_t dt + \beta_t dW_t) + 0 \cdot \beta_t dt$$

$$= (U_t^T Y_t + U_t^T \alpha_t) dt + U_t^T \beta_t dW_t,$$

where $(U_j, Y_j)$, $j = 1, \ldots, R$ is the quadratic covariation of $U^j$ and $Y^j$. Since $X$ is assumed to satisfy (2.1), the uniqueness of the representation of Itô processes implies

$$U_t^T Y_t + U_t^T \alpha_t = a(t, U_t^T Y_t)$$

$$U_t^T \beta_t = b(t, U_t^T Y_t).$$

Now, using $U_t U_t^T = 0 \in \mathbb{R}^{R \times R}$ and $U_t U_t^T = I \in \mathbb{R}^{R \times R}$ for almost every $t \in [0, T]$, these equalities imply

$$\alpha_t = U_t a(t, U_t^T Y_t) \quad \text{and} \quad \beta_t = U_t b(t, U_t^T Y_t).$$

Moreover, $U_t$ is absolutely continuous and by assumption $Y_t$ is a.s. continuous. This implies that $\alpha_t$ and $\beta_t$ have a continuous path almost surely, and hence (2.7) follows. In turn, from (2.12) we find

$$C_{Y_t} \hat{U}_t = E[Y_t a(t, U_t^T Y_t)] - E[Y_t a(t, U_t^T Y_t)] U_t^T U_t$$

$$= E[Y_t a(t, U_t^T Y_t)] (I_{d \times d} - U_t^T U_t),$$

with $C_{Y_t} := E[Y_t Y_t^T]$. Hence, from the orthogonality assumption of $U$ we have

$$C_{Y_t} \hat{U}_t = E[Y_t a(t, U_t^T Y_t) (I_{d \times d} - P_{U_t^T}^{row}).$$

This completes our consistency argument.

2.2 DO equations interpreted as a projected dynamics

The DO equations (2.6)–(2.7) are posed as a system of equations for the separate factors $U$ and $Y$. We now discuss what equation the DO approximation $X = \sum_{j=1}^R U^j Y_j$ should satisfy. In other words, we aim to derive an equation for $X$ in the ambient space, independent of the parametrisation $(U, Y)$.

For this purpose, we substitute (2.6) and (2.7) into (2.9); we obtain

$$dX_t = ((I_{d \times d} - P_{U_t}^{row}) E[Y_t a(t, U_t^T Y_t)] C_{Y_t}^{-1} Y_t + P_{U_t}^{row} a(t, U_t^T Y_t)) dt + P_{U_t}^{row} b(t, U_t^T Y_t) dW_t$$

$$= ((I_{d \times d} - P_{U_t}^{row}) [P_{Y_t} a(t, U_t^T Y_t)] + P_{U_t}^{row} a(t, U_t^T Y_t)) dt + P_{U_t}^{row} b(t, U_t^T Y_t) dW_t,$$

where $P_{Y_t} a(t, X_t) \in \mathbb{R}^d$ is the application of the $L^2(\Omega)$-orthogonal projection $P_{Y_t} : L^2(\Omega) \to \text{span}\{Y_t^1, \ldots, Y_t^R\}$ to each component of $a(t, X_t) \in \mathbb{R}^d$. To derive a parameter-independent equation, we seek a parameter-free expression of the projections $P_{U_t}$ and $P_{Y_t}$.
Given $X_t \in L^2(\Omega; \mathbb{R}^d)$, $t \in [0, T]$, let $\mathcal{P}_{U(X_t)}: \mathbb{R}^d \rightarrow \text{Im}(\mathbb{E}[X_t \cdot]) \subset \mathbb{R}^d$ be the orthogonal projection matrix to the image of the mapping $\mathbb{E}[X_t \cdot]: L^2(\Omega) \rightarrow \mathbb{R}^d$, and let $\mathcal{P}_{Y(X_t)}: L^2(\Omega) \rightarrow \text{Im}(K_t \cdot) \subset L^2(\Omega)$ be the $L^2(\Omega)$-orthogonal projection to the image of the mapping $K_t \cdot: \mathbb{R}^d \rightarrow L^2(\Omega)$. In Lemma 2.3 we will show $\dim(\text{Im}(\mathcal{P}_{Y(X_t)})) = \dim(\text{Im}(\mathbb{E}[X_t \cdot]), i.e., $\text{Im}(K_t \cdot)$ is a finite-dimensional linear subspace of $L^2(\Omega)$, and thus $\mathcal{P}_{Y(X_t)}$ is well defined.

In the case of DO approximation $X_t = U_t^\top Y_t$, we have $\text{Im}(\mathbb{E}[X_t \cdot]) = \text{span}\{U_t^1, \ldots, U_t^R\}$ and $\text{Im}(K_t \cdot) = \text{span}\{Y_t^1, \ldots, Y_t^R\}$, we conclude that $\mathcal{P}_{U(X_t)}v = U_t^\top U_t v = P_{\text{sym}} v, v \in \mathbb{R}^d$ and $\mathcal{P}_{Y(X_t)}w = \mathbb{E}[w Y_t^\top C_{Y_t}] Y_t = P_{Y_t} w, w \in L^2(\Omega)$, so that (2.15) can be rewritten as

$$dX_t = \left(\left(I_{d \times d} - \mathcal{P}_{U(X_t)}\right)\left[\mathcal{P}_{Y(X_t)} a(t, U_t^\top Y_t)\right] + \mathcal{P}_{U(X_t)} a(t, X_t)\right) dt + \mathcal{P}_{U(X_t)} b(t, U_t^\top Y_t) dW_t.$$  \hfill{(2.16)}

This equation, derived from (2.6) and (2.7), does not depend on the parametrisation of the pair $(U_t, Y_t)$ and could be taken as an alternative definition of DO approximation. More precisely, given any process $X = (X_t)_{t \in [0, T]}$ with $X_t \in L^2(\Omega; \mathbb{R}^d)$ for $t \in [0, T]$, we can define the following stochastic process:

$$dX_t = \left(\left(I_{d \times d} - \mathcal{P}_{U(X_t)}\right)\left[\mathcal{P}_{Y(X_t)} a(t, X_t)\right] + \mathcal{P}_{U(X_t)} a(t, X_t)\right) dt + \mathcal{P}_{U(X_t)} b(t, X_t) dW_t. \hfill{(2.17)}$$

It is worth noticing that (2.17) is a McKean-Vlasov-type SDE since the evolution of $X_t$ depends on the law of the process.

Finally, to speak of the rank of the solution $X$ to (2.17) we note the following. Given $\tilde{X} \in L^2(\Omega; \mathbb{R}^d)$ the mapping $K_{\tilde{X}}: \mathbb{R}^d \rightarrow L^2(\Omega)$ defined by $K_{\tilde{X}} v := \tilde{X}^\top v$ for $v \in \mathbb{R}^d$ is by definition finite rank. Moreover, the operator $K_{\tilde{X}}: \mathbb{E}[\tilde{X}]: L^2(\Omega) \rightarrow \mathbb{R}^d$ is the adjoint of $K_{\tilde{X}}$:

$$\mathbb{E}[g(K_{\tilde{X}} v)] = \mathbb{E}[g(\tilde{X}^\top v)] = \mathbb{E}[w^\top \tilde{X} y] = v^\top K_{\tilde{X}}^* y, \forall y \in L^2(\Omega), \forall v \in \mathbb{R}^d$$

The operator $K_{\tilde{X}}^* K_{\tilde{X}}: \mathbb{R}^d \rightarrow \mathbb{R}^d$ is given by $K_{\tilde{X}}^* K_{\tilde{X}} v = \mathbb{E}[\tilde{X}^\top] v$ for $v \in \mathbb{R}^d$. The following lemma characterises the rank of these operators.

**Lemma 2.3.** Given $\tilde{X} \in L^2(\Omega; \mathbb{R}^d)$, we have $\text{rank}(K_{\tilde{X}}^* K_{\tilde{X}}) = \text{rank}(K_{\tilde{X}}) = \text{rank}(K_{\tilde{X}}^*)$.

**Proof.** First, notice that we have $\text{ker}(K_{\tilde{X}}^*) = \text{Im}(K_{\tilde{X}}^*)$, where $\perp$ is the orthogonal complement with respect to the Euclidean inner product. Hence, we have $\text{ker}(K_{\tilde{X}}^*) |_{\text{Im}(K_{\tilde{X}})} = \{0\}$. Thus, the rank-nullity theorem implies

$$\dim(\text{Im}(K_{\tilde{X}}^*) |_{\text{Im}(K_{\tilde{X}})}) = \dim(\text{Im}(K_{\tilde{X}})).$$

Therefore $\text{rank}(K_{\tilde{X}}^* K_{\tilde{X}}) = \text{rank}(K_{\tilde{X}})$. Moreover, from $\text{rank}(K_{\tilde{X}}^*) = \text{rank}(K_{\tilde{X}}^*)$ (see for example [12, Theorem III.4.13]), the proof is complete. \hspace{1cm} \Box

In view of the lemma above, we call $\dim(\text{Im}(\mathbb{E}[X_t \cdot]))$, equivalently $\dim(\text{Im}((X_t^\tau \cdot)))$ and $\text{rank}(\mathbb{E}[X_t X_t^\tau])$, rank of $X_t$.

**Definition 2.4** (DLR solution of rank $R$). A process $X: [0, T] \rightarrow L^2(\Omega; \mathbb{R}^d)$ is called a DLR solution of rank $R$ to (2.1) for an initial datum $X_0 \in L^2(\Omega; \mathbb{R}^d)$ if it satisfies (2.17), $\text{dim}(\text{Im}(\mathbb{E}[X_t \cdot])) = R$ for some $R \in \mathbb{N}$ for all $t \in [0, T]$, and $X$ has almost surely continuous paths.

The parameter-independent formulation (2.17) corresponds to the projected dynamics in the DLR literature; see [18], also [15, Proposition 2]. Notice however that in our formulation, only the projector $\mathcal{P}_{U(X_t)}$ is applied to the diffusion term $b(t, X_t) dW_t$, instead of the full projector $\mathcal{P}_{U(X_t)} + \mathcal{P}_{Y(X_t)} - \mathcal{P}_{U(X_t)} \mathcal{P}_{Y(X_t)}$.

If we naively wrote the projected dynamics following the standard DLR approach, we would end up with the alternative formal expression

$$dX_t = \left(\mathcal{P}_{U(X_t)} + \mathcal{P}_{Y(X_t)} - \mathcal{P}_{U(X_t)} \mathcal{P}_{Y(X_t)}\right) [a(t, X_t) dt + b(t, X_t) dW_t], \hfill{(2.18)}$$

6
Proof. \( \text{implies} \)

Let the singular value decomposition of \( \mu \) be

Thus, we have

However, it is not obvious how to give a rigorous meaning to the term \( \partial_t \mathcal{X}_t \) as an Itô integral and for this reason we do not pursue the formulation (2.18) further.

To confirm that (2.17) is nevertheless a sensible projected dynamics, let us ask ourselves the following question: if the solution \( X_t \) of (2.17) satisfies

is the right hand side of (2.17) consistent with this structure of \( X_t \)? In the following, we will see that the answer is affirmative, which supports the validity of (2.17), and thus (2.6) and (2.7), as a correct DLRA formulation for SDEs.

In view of Lemma 2.3, we study the rank of the matrix \( E[X_0 X_0^T] \), where \( X_0 \) is given by (2.17). To do this, we will show that \( \frac{d}{dt} (E[X_t X_t^T]) \) is in a tangent space of the rank-\( R \) manifold, i.e., the manifold of \( d \times d \) matrices with rank equal to \( R \), at \( E[X_0 X_0^T] \). For \( j, k = 1, \ldots, d \), Itô’s formula implies

where \( \mu_k^s := [(I_{d \times d} - \mathcal{P}(X_0)) \mathcal{P}(X_0) a(t, X_0)] + \mathcal{P}(X_0) a(t, X_0) \) and \( \Sigma_k^s := [\mathcal{P}(X_0) b(t, X_0)]_{k \ell} \).

Thus, we have

with \( \mu_t := [\mu_k^s]_{k=1, \ldots, d} \in \mathbb{R}^d \) and \( \Sigma_t := [\Sigma_k^s]_{k=1, \ldots, d} \in \mathbb{R}^{d \times m} \).

On the other hand, from [39, Proposition 2.1] we know that the tangent space of a rank \( R \) manifold at \( E[X X^T] = Q \text{diag}(\gamma_1, \ldots, \gamma_R) Q^T \) can be characterized as

To conclude \( \frac{d}{dt} (E[X_t X_t^T]) \in T_{E[X_0 X_0^T]} \mathcal{M} \) we will use the following result.

**Lemma 2.5.** Let the singular value decomposition \( E[X X^T] = Q \text{diag}(\gamma_1, \ldots, \gamma_R) Q^T \), with \( \gamma_1, \ldots, \gamma_R > 0 \) be given, where \( Q \in \mathbb{R}^{d \times R} \) is a matrix consisting of \( R \) orthonormal columns \( q_1, \ldots, q_R \in \mathbb{R}^d \). Then, the canonical expansion of the finite rank operator \( E[X \cdot] : L^2(\Omega) \rightarrow \mathbb{R}^d \) is given by

where \( \varphi_k := \gamma_k^{-1/2} X_k q_k \), \( k = 1, \ldots, R \) is an orthonormal basis of \( \text{Im}(X^T \cdot) \subset L^2(\Omega) \).

**Proof.** From

we have \( \{q_k\}_{k=1}^R \subset \text{Im}(E[X \cdot]) \), and thus \( \{q_k\}_{k=1}^R \) is an orthonormal basis of \( \text{Im}(E[X \cdot]) \subset \mathbb{R}^d \). Thus, with some coefficients \( \{c_k\}_{k=1}^R \subset \mathbb{R} \) we have for any \( y \in L^2(\Omega) \) a representation

which implies

The functions \( \varphi_k := \gamma_k^{-1/2} X_k q_k \), \( k = 1, \ldots, R \) are orthonormal in \( L^2(\Omega) \), and thus form an orthonormal basis in the \( R \)-dimensional subspace \( \text{Im}(X^T \cdot) \). \( \square \)
The equation (2.19) together with this lemma shows \( \frac{d}{dt}(E[X_t X_t^\top]) \in T_{E[X_t X_t^\top]}M \). Indeed, the first term of the right hand side of (2.19) can be written as

\[
E[X_t \mu_t] = E[X_t (\mathcal{P}_{Y(X_t)} a(t, X_t))^\top (I_{d \times d} - \mathcal{P}_{U(X_t)})] + E[X_t a(t, X_t)] P_{U(X_t)}
\]

where, using Lemma 2.5, we may write

\[
Q_t B_t (I_{d \times d} - Q_t Q_t^\top) + Q_t C_t Q_t^\top,
\]

Similarly, we have

\[
E[X_t \mu_t^\top] = Q_t V_t + Q_t A_t Q_t^\top.
\]

Hence, if \( E[X_t X_t^\top] \) is of rank \( R \) then by its derivative (2.19), which was derived from the projected dynamics (2.17), lies indeed in \( T_{E[X_t X_t^\top]} M \). This consistency supports the validity of the formulation (2.17), and in turn that of the DO equations (2.6) and (2.7).

### 2.3 Equivalence of DO and DLR formulations

In the previous section, we showed that if there exists a strong DO solution \( (U_t, Y_t) \) to (2.1), then the corresponding DO approximation \( X_t = U_t^\top Y_t \) satisfies (2.17). We now investigate the reverse question: if \( X_t \) is a rank-\( R \) solution of (2.17) (DLR solution of rank \( R \) of (2.1)) does there exist a DO solution \( (U, Y) \) such that \( X = U^\top Y \)?

First, we need the following bound for the DLR solution.

**Lemma 2.6.** Let a rank-\( R \) DLR solution \( X_t, t \in [0, T] \), to (2.1) with \( X_0 \in L^2(\Omega; \mathbb{R}^d) \) be given. For all \( t \in [0, T] \), \( X_t \) satisfies

\[
E[|X_t|^2] \leq 3 \left( E[|X_0|^2] + C_{lb} T(T+1) \right) \exp \left( 3C_{lb} T(T+1) \right) = M(T)
\]

**Proof.** Taking the squared \( L^2(\Omega) \)-norm of \( X_t \) and using (2.17) in integral form, together with Itô’s isometry, Jensen’s inequality, and Assumption 2, we have

\[
E[|X_t|^2] = E[|X_0|^2] + \int_0^t \left( (I_{d \times d} - \mathcal{P}_{U(X_s)}) [\mathcal{P}_{Y(X_s)} a(s, X_s)] + \mathcal{P}_{U(X_s)} a(s, X_s) \right) ds
\]

\[
+ 3 E\left[ \int_0^t (I_{d \times d} - \mathcal{P}_{U(X_s)}) \mathcal{P}_{Y(X_s)} a(s, X_s) + \mathcal{P}_{U(X_s)} a(s, X_s) ds \right] ^2
\]

\[
\leq 3 E[|X_0|^2] + 3 E\left[ \int_0^t (I_{d \times d} - \mathcal{P}_{U(X_s)}) \mathcal{P}_{Y(X_s)} a(s, X_s) + \mathcal{P}_{U(X_s)} a(s, X_s) ds \right] ^2
\]

\[
+ 3 \int_0^t E[|\mathcal{P}_{U(X_s)} a(s, X_s)|^2] ds
\]

\[
\leq 3 E[|X_0|^2] + 3 T \int_0^t E[|\mathcal{P}_{Y(X_s)} a(s, X_s) + \mathcal{P}_{U(X_s)} a(s, X_s) |^2] ds
\]

\[
+ 3 \int_0^t E[|\mathcal{P}_{U(X_s)} a(s, X_s)|^2] ds
\]

\[
\leq 3 E[|X_0|^2] + 3 C_{lb} (T+1) \int_0^t (1 + E[|X_s|^2]) ds.
\]

Hence, Gronwall’s lemma implies the statement.

The following theorem gives the uniqueness of the DLR solution.

**Theorem 2.7.** Let \( X_0 \in L^2(\Omega; \mathbb{R}^d) \) be such that \( \dim(\text{Im}(E[|X_0|^2])) = R \). Suppose that two DLR solutions \( X_t \) and \( Z_t \) of rank \( R \) to (2.1) with initial datum \( X_0 \) exist on \([0, T]\). Then \( X_t \) and \( Z_t \) are indistinguishable.
Proof. The processes $X_t$ and $Z_t$ are assumed to satisfy
\[
\begin{align*}
dX_t &= ((I_{d \times d} - \mathcal{P}_t)\mathcal{P}_t a(t, X_t) + \mathcal{P}_t b(t, X_t))
dt + \mathcal{P}_t b(t, X_t) \, dB_t \\
&= \mathcal{P}_t a(t, X_t)
\end{align*}
\]
and
\[
\begin{align*}
dZ_t &= ((I_{d \times d} - \mathcal{P}_t)\mathcal{P}_t a(t, Z_t) + \mathcal{P}_t b(t, Z_t))
dt + \mathcal{P}_t b(t, Z_t) \, dB_t, \\
&= \mathcal{P}_t a(t, Z_t)
\end{align*}
\]
respectively, for the same initial datum $X_0$. This implies that
\[
\begin{align*}
\mathbb{E}[|X_t - Z_t|^2] &\leq \mathbb{E}\left[\int_0^t ((I_{d \times d} - \mathcal{P}_t)\mathcal{P}_t a(s, X_s) - \mathcal{P}_t a(s, Z_s)) \, ds \right] \\
&\quad + \int_0^t \mathbb{E}[\mathcal{P}_t b(s, X_s) - \mathcal{P}_t b(s, Z_s)] \, dB_s^2 \\
&\quad + 2\mathbb{E}\left[\int_0^t (\mathcal{P}_t a(s, X_s) - \mathcal{P}_t a(s, Z_s)) \, dB_s \right]^2 \\
&\quad + 2\mathbb{E}\left[\int_0^t \mathcal{P}_t b(s, X_s) - \mathcal{P}_t b(s, Z_s)] \, dB_s \right]^2
\end{align*}
\]
(2.21)
Denote by $\gamma := \inf_{s \in [0, T]} \sigma_{R(\mathbb{E}[X_t, X_t^T])]$ the infimum over time of the $R$-th singular value of the matrix $\mathbb{E}[X_t, X_t^T] \in \mathbb{R}^{R \times R}$, where for all $t$ we are considering the singular values in a decreasing order. We have $\gamma > 0$. To see this, first note that, from Lemma 2.3 the rank of $\mathbb{E}[X_t, X_t^T]$ is the same as the rank of $X_t$. But from the definition of DLR solution, $X_t$ has always rank $R$, and moreover, the continuity of $X_t$ implies continuity of $\sigma_{R(\mathbb{E}[X_t, X_t^T])}$ on $[0, T]$. Hence $\gamma > 0$ follows; see also [14, Lemma 2.1].

Using Assumptions 1–2, Lemma 2.6, Itô’s isometry and Jensen’s inequality to (2.21), we can take $t' \in (0, T]$ such that
\[
\begin{align*}
\mathbb{E}[(X_{t'} - Z_{t'})^2] &\leq 4C_{gb}(1 + M(T))T \int_0^{t'} \mathbb{E}[\mathcal{P}_t a - \mathcal{P}_t Z_s]^2 \, ds \\
&\quad + 4C_{gb}(1 + M(T)) \int_0^{t'} \mathbb{E}[\mathcal{P}_t b - \mathcal{P}_t Z_s]^2 \, ds \\
&\quad + 4(T + 1)C_{Lip} \int_0^{t'} \mathbb{E}[Z_s - X_s]^2 \, ds \\
&\quad \leq 8(T + 1)[C_{gb}(1 + M(T)) + 2C_{Lip} M(T)] t' \\
&\quad < \frac{\gamma^2}{R^2}
\end{align*}
\]
where we used $M(T)$ as defined in Lemma 2.6. Then, Proposition A.2 is applicable for all $s \in (0, t')$, and for such $s$ we have
\[
\begin{align*}
\mathbb{E}[(\mathcal{P}_t a - \mathcal{P}_t Z_s)^2] &\leq \left(\frac{3R}{\gamma}\right)^2 \mathbb{E}[|X_s - Z_s|^2] \mathbb{E}[v_{L^2(\Omega, \mathbb{R}^d)}^4] \quad \text{for any } v \in L^2(\Omega, \mathbb{R}^d)
\end{align*}
\]
(2.22)
We will show that there exists a unique absolutely continuous curve. The proof follows closely the arguments in [14, Lemma 2.3, Corollary 2.4, and Lemma 2.5].

**Proof.**

\[ \Theta \] and \( X \) satisfy the DLR equation (2.17) and the DO equation (2.6)–(2.7), which we stated as a corollary. The equation (2.16), and thus (2.17). Hence, Theorem 2.7 gives the sought equivalence between the DLR equation (2.17) and the DO equation (2.6)–(2.7), which we state as a corollary.

**Corollary 2.8.** Let \( X_0 \in L^2(\Omega; \mathbb{R}^d) \) with \( \text{dim}(\text{Im}(\mathbb{E}[X_0])) = R \). Suppose that a DLR solution \( X_t \) of rank \( R \) to (2.1) and a strong DO solution \((U,Y)\) exist on \([0,T]\), both with initial datum \( X_0 \). Then, \( X_t \) and the DO approximation \( X_t = U_t^{\top} Y_t \) are indistinguishable; see for example [29, Theorem 2].

Given a strong DO solution \((U,Y)\) to (2.1), the corresponding DO approximation \( X_t \) satisfies the equation (2.16), and thus (2.17). Hence, Theorem 2.7 gives the sought equivalence between the DLR equation (2.17) and the DO equation (2.6)–(2.7), which we state as a corollary.

Moreover, the DO solution giving the same DLR solution is unique up to a rotation matrix. See also [14, Section 2.2] for a similar result.

**Proposition 2.9.** Assume that a DLR solution \( X_t \) of rank \( R \) to (2.1) with initial datum \( X_0 \in [L^2(\Omega)]^d \) exists for all \( t \in [0,T] \). Suppose there exist two strong DO solutions \((U_t,Y_t)\) and \((V_t,Z_t)\). Then there exists a unique orthogonal matrix \( \Theta \in \mathbb{R}^{R \times R} \) such that \((V_t,Z_t) = (\Theta U_t, \Theta Y_t)\).

**Proof.** The proof follows closely the arguments in [14, Lemma 2.3, Corollary 2.4, and Lemma 2.5]. We will show that there exists a unique absolutely continuous curve \( t \to \Theta(t) \) with orthogonal matrix \( \Theta(t) \in \mathbb{R}^{R \times R} \) for all \( t \) such that \((V_t,Z_t) = (\Theta(t) U_t, \Theta(t) Y_t)\), and that \( \Theta(t) \) is a constant in \( t \). First, we will derive an equation that \( \Theta(t) \) must satisfy. Suppose that \( \Theta(t) \) exists. Note that, since both \( U_t^{\top} Y_t \) and \( V_t^{\top} Z_t \) satisfy (2.16), Theorem 2.7 implies \( X_t = U_t^{\top} Y_t = V_t^{\top} Z_t \) for all \( t \) and \( a.s. \) Then since \((V_t,Z_t)\) is a strong DO solution, one must have

\[
\dot{U}_t = (\Theta(t) V_t) = \dot{\Theta}^\top(t) V_t + \Theta^\top(t) \dot{V}_t \quad \text{for a.e.} \quad t \in [0,T].
\]  

(2.24)

As \( U_t \dot{U}_t^{\top} = 0 \) and \( U_t U_t^{\top} = I_{R \times R} \), from \( U_t = \Theta^\top(t) V_t \) it follows

\[
0 = \Theta^\top(t) V_t \left( \dot{\Theta}^\top(t) V_t + \Theta^\top(t) \dot{V}_t \right)^{\top} = \Theta^\top(t) \left( \dot{\Theta}(t) + V_t \dot{V}_t^{\top} \Theta(t) \right).
\]

(2.25)

Using orthogonality of \( \Theta(t) \) and \( V_t \dot{V}_t^{\top} = 0 \), we obtain the following differential equation that \( \Theta(t) \) has to satisfy:

\[
\dot{\Theta}(t) = 0 \quad \text{for a.e.} \quad t \in [0,T] \quad \text{with} \quad \Theta(0) = \Theta_*.
\]

(2.26)

where \( \Theta_* \) is an orthogonal matrix. But this equation has a unique solution \( \Theta(t) = \Theta_* \), which is an orthogonal matrix. Hence, going back the argument above, \( \Theta \) satisfies (2.24). The absolute continuity of \( U \) and \( \Theta V \) yields \( U_t = \Theta(t) V_t + C \) for all \( t \in [0,T] \), with some matrix \( C \in \mathbb{R}^{R \times R} \).
Such \( \Theta_* \) that makes \( C = 0 \) can be constructed explicitly. Since \( U_t, V_t \) are deterministic, from \( U_0 Y_0 = V_0^T Z_0 \) we must have

\[
U_0^T = V_0^T R^{-1} C_{Y_0}^{-1}.
\]

Take \( \Theta_* = \mathbb{E}[Z_0 Y_0^T] C_{Y_0}^{-1} \). Then, from the argument above \( U_t = \Theta V_t \) holds for all \( t \in [0, T] \). We conclude the proof by noting the orthogonality of \( \Theta_* \):

\[
I_{R \times R} = U_0 U_0^T = \Theta_1^T V_0 V_0^T \Theta_1 = \Theta_1^T \Theta_*.
\]

\[ \square \]

**Remark 2.10.** In Section 3, under Assumptions 1–3 we will show that there exists a unique strong DO solution \((U, Y)\) in a certain interval \([0, T]\). Hence, in view of Theorem 2.7 and Corollary 2.8, a unique DLR solution \(X_t\) exists on \([0, T]\) and moreover, given \( X_t \), we can always find a strong DO solution \((U, Y)\) such that \( X_t = U_t^T Y_t \).

### 3 Local existence and uniqueness

The equations (2.6) and (2.7) define a non-standard system of stochastic differential equations. Notice that in (2.6), the matrix-valued function \([L^2(\Omega)]^R \ni Y \mapsto C_{Y}^{-1} \in R^{R \times R}\) is not defined everywhere in \([L^2(\Omega)]^R\). Moreover, the vector field \( \mathbb{E}[Y_t a(t, X_t)^\top] \) requires taking the expectation, and thus depends on the knowledge of all the paths of \( Y_t \). Hence, the vector fields that define the DO equation are not defined path-wise a priori. This setting makes the existence and uniqueness result of DLR solutions non-trivial.

To establish existence and uniqueness of solutions of (2.6) and (2.7) given initial datum \((U_0, Y_0)\), we follow a fixed-point argument. We will define a sequence of Picard iterates, which we recall that \( P_{\mathcal{F}_s}\) is the projection-matrix onto the row space \( \text{span}\{U_1, \ldots, U_R\} \subset \mathbb{R}^d \) of \( U_s \). Note that the stochastic integral \( \int_0^t U_s b(s, U_s^T Y_s) dW_s \) is well defined, since \( Y \in L^2(\Omega; C([0, t]; \mathbb{R}^d)) \) is (indistinguishable from) a progressively measurable process.

We will construct a unique fixed point of \( F_1 \) and \( F_2 \). Because of the aforementioned difficulties, defining a suitable sequence of Picard iterates requires some care. Let us consider \( \varphi \in \mathbb{R}^{R \times d} \) with \( d \geq R \) having orthogonal row vectors, and \( \xi = (\xi_1, \ldots, \xi_R) \in [L^2(\Omega)]^R \), having linearly independent components, \( \mathcal{F}_0\)-measurable with \( \rho^2 := \|\varphi\|_{L^2(\Omega)}^2 \) and \( \gamma := \|C_{\varphi}^{-1}\|_F \). We force iterations to belong to balls in \( \mathbb{R}^{R \times d} \) and \([L^2(\Omega)]^R\) around \( \varphi \) and \( \xi \), respectively, of a suitable radius \( \eta \).

For the ball in \( \mathbb{R}^{R \times d} \), to invoke Proposition A.1 in the appendix, we equip \( \mathbb{R}^{R \times d} = [\mathbb{R}^d]^R \) with the norm \( \|U\|_{[\mathbb{R}^d]^R} = \sum_{j=1}^R \|U_j\|^2 \). For \( \varphi = (\varphi^1, \ldots, \varphi^R)^\top \) orthogonal, we have \( \|\varphi\|_{[\mathbb{R}^d]^R} = \sqrt{R} \), and

\[
Z_\varphi := (\varphi^j(\varphi^k)^\top)_{j,k=1,\ldots,R} = \varphi \varphi^\top = I_{R \times R},
\]
so with \( \eta_1 := \eta(\sqrt{R}, \sqrt{R}) \) as in (A.1), \( \nu \in B_\eta(\varphi) \) implies \( \|\nu v^{\top}\|_F \leq 2 \). Hence, the projection \( (I_{d \times d} - T_{\nu}^{\varphi}) \) is Lipschitz continuous on \( B_{\eta_1}(\varphi) \); see Lemma A.3.

For the ball in \( [L^2(\Omega)]^R \), first note that, since \( [L^2(\Omega)]^R \ni Z \mapsto \mathbb{E}[ZZ^{\top}]^{-1} \in \mathbb{R}^{d \times d} \) is continuous in the open set \( \Gamma = \{ Z \in [L^2(\Omega)]^R \mid \det(\mathbb{E}[ZZ^{\top}]) \neq 0 \} \) (cf. [14, Proof of Lemma 3.5]), and \( \xi \in \Gamma \), via Proposition A.1 there exists a ball \( B_{\eta_2}(\xi) \) in \( [L^2(\Omega)]^R \) around \( \xi \) with radius \( \eta_2 := \eta(\rho, \gamma) > 0 \) such that any \( w \in B_{\eta_2}(\xi) \) has linearly independent components and \( \|C_{\nu}^{-1}\|_F \leq 2 \gamma \).

Abusing the notation slightly, we let

\[
\eta = \eta(\rho, \gamma) := \min\{\eta(\sqrt{R}, \sqrt{R}), \eta(\rho, \gamma)\}. 
\]

Proposition A.1 tells us that \( \eta \) is non-increasing in both variables \( \rho \) and \( \gamma \).

We want to define sequences \( Y^{(n)}_t \in B_\eta(\xi) \) and \( U^{(n)}_t \in B_\eta(\varphi) \) for \( t \in [0, \delta] \) with a suitable \( \delta = \delta(\varphi, \xi) > 0 \). To this extent, let \( (U^{(0)}_t, Y^{(0)}_t) := (\varphi, \xi) \), \( U^{(n+1)}_t := F_1(U^{(n)}_t, Y^{(n)}_t)(t) \), \( Y^{(n+1)}_t := F_2(U^{(n)}_t, Y^{(n)}_t)(t) \), and \( X^{(n)}_t := (U^{(n)}_t)^\top Y^{(n)}_t \), \( n = 0, 1, \ldots \) for \( t \in [0, \delta] \) with

\[
\delta := \min\{1, \frac{\min\{1, \eta^2\}}{36RC_{\text{gb}}(1 + 3R(3\rho^2 + 1))}, \frac{\min\{\eta^2, R\}}{8\gamma(3\rho^2 + 1)C_{\text{gb}}(1 + 3R(3\rho^2 + 1))} \}.
\]

Moreover, let

\[
\mathbb{D}_{\text{det}} := \left\{ \mathbf{V} \in C([0, \delta]; \mathbb{R}^{d \times d}) \mid \sup_{0 \leq t \leq \delta} \|\mathbf{V}_t\|_F^2 \leq 3R, \text{ and } \mathbf{V}_t \in B_\eta(\varphi) \text{ for } t \in [0, \delta] \right\}
\]

and

\[
\mathbb{D}_{\text{sto}} := \left\{ \mathbf{Z} \in L^2(\Omega; C([0, \delta]; \mathbb{R}^R)) \mid \mathbf{Z} \text{ is } \mathcal{F}_t\text{-adapted, } \mathbb{E}\left[ \sup_{0 \leq t \leq \delta} \|\mathbf{Z}_t\|^2 \right] \leq 3\rho^2 + 1, \text{ and } \mathbf{Z}_t \in B_\eta(\xi) \text{ for } t \in [0, \delta] \right\}
\]

The following lemma shows that our Picard sequence takes value in \( \mathbb{D}_{\text{det}} \times \mathbb{D}_{\text{sto}} \).

**Lemma 3.1.** Under Assumptions 2-3, the sequence \( \{(U^{(n)}_t, Y^{(n)}_t)\}_{n \geq 0} \) defined above satisfies

\[
(U^{(n)}_t, Y^{(n)}_t) \in \mathbb{D}_{\text{det}} \times \mathbb{D}_{\text{sto}} \text{ for all } n \in \mathbb{N},
\]

where \( \delta = \delta(C_{\text{gb}}, d, \eta, R, \rho) \) is defined in (3.3).

**Proof.** We have \( \|\varphi\|_F^2 = R \), \( \|\xi\|_{L^2[0,1]}^2 = \rho^2 \), and trivially \( \xi \in B_\eta(\xi) \) and \( \varphi \in B_\eta(\varphi) \), where \( \eta = \eta(\rho, \gamma) \) is built as in Proposition A.1. Moreover, \( \xi \) is \( \mathcal{F}_t\)-adapted thanks to Assumption 3. Thus, \( (U^{(0)}_t, Y^{(0)}_t) \in \mathbb{D}_{\text{det}} \times \mathbb{D}_{\text{sto}} \). Assume \( (U^{(n)}_t, Y^{(n)}_t) \in \mathbb{D}_{\text{det}} \times \mathbb{D}_{\text{sto}} \) for \( n \in \mathbb{N} \). Then, from Assumption 2, we see that \( U^{(n+1)}_t \) and \( Y^{(n+1)}_t \) are well defined, and that \( Y^{(n+1)}_t \) is \( \mathcal{F}_t\)-adapted. Moreover, from \( \mathbb{E}\left[ \sup_{0 \leq s \leq \delta} \|Y^{(n)}_s\|^2 \right] < \infty \), Doob’s martingale inequality, Itô’s isometry, and the inequality \( \|AB\|_F \leq \|A\|_2 \|B\|_F \) for \( A \in \mathbb{R}^{n \times m}, B \in \mathbb{R}^{m \times p} \) imply

\[
\mathbb{E}\left[ \sup_{0 \leq t \leq \delta} \|Y^{(n+1)}_t\|^2 \right] 
\leq 3\mathbb{E}\left[ \|\xi\|^2 \right] + 3\mathbb{E}\left[ \sup_{0 \leq s \leq \delta} \int_0^t \|U^{(n)}_s\|^2 \|a(s, X^{(n)}_s)\|^2 \mathrm{d}s + \sup_{0 \leq t \leq \delta} \int_0^t \|U^{(n)}_s b(s, X^{(n)}_s)\|_2^2 \mathrm{d}s \right] 
\leq 3\rho^2 + 3\mathbb{E}\left[ \int_0^\delta \|a(s, X^{(n)}_s)\|^2 \mathrm{d}s \right] + 12\mathbb{E}\left[ \int_0^\delta \|U^{(n)}_s b(s, X^{(n)}_s)\|_2^2 \mathrm{d}s \right] 
\leq 3\rho^2 + 36RC_{\text{gb}}(1 + \mathbb{E}\left[ \sup_{0 \leq s \leq \delta} \|X^{(n)}_s\|^2 \right]) \delta 
\leq 3\rho^2 + 36RC_{\text{gb}}(1 + 3R(3\rho^2 + 1)) \delta 
\leq 3\rho^2 + 36RC_{\text{gb}}(1 + 3R(3\rho^2 + 1)) \delta \leq 3\rho^2 + 1,
\]
where in the penultimate line we used \( \delta \leq 1 \), and in the last line \( |a(s,x)|^2 + |b(s,x)|^2 \leq C_{\text{Lip}}(1 + |x|^2) \) together with the definition of \( \delta \). Similarly, we have

\[
\mathbb{E}\left[ \sup_{0 \leq t \leq \delta} |Y^{(n+1)}_t - \xi|^2 \right] \leq 2\mathbb{E}\left[ \sup_{0 \leq t \leq \delta} t \int_0^t \|U_s^{(n)}\|^2_2 |a(s,X_s^{(n)})|^2 ds + \sup_{0 \leq t \leq \delta} \int_0^t U_s^{(n)}b(s,X_s^{(n)})dW_s \right] \\
\leq 24C_{\text{Lip}}R(1 + 3R(3\rho^2 + 1))\delta \leq \eta^2.
\]

We readily have \( Y^{(n+1)} \in L^2(\Omega;C([0,\delta];\mathbb{R}^d)) \) and hence \( Y^{(n+1)} \in \mathbb{D}_{\text{sto}} \). Likewise, we have \( U^{(n+1)} \in \mathbb{D}_{\text{det}} \), since

\[
\sup_{0 \leq t \leq \delta} \|U_t^{(n+1)}\|_F \leq 2R + 2\sup_{0 \leq t \leq \delta} t \int_0^t \|C_u^{-1}Y_s^{(n)}a(s,X_s^{(n)})^\top(I_{d \times d} - P_{\text{row}}u^{(n)})\|_F^2 ds \\
\leq 2R + 8\delta^2\int_0^\delta \mathbb{E}\left[ \sup_{0 \leq s \leq \delta} |Y_s^{(n)}|^2 \right] \mathbb{E}(\sup_{0 \leq s \leq \delta} |a(s,X_s^{(n)})|^2)(\sqrt{d} + \sqrt{R})^2 ds \\
\leq 2R + 8\delta^2(3\rho^2 + 1)C_{\text{Lip}}(1 + 3R(3\rho^2 + 1))(\sqrt{d} + \sqrt{R})^2 \\
\leq 3R,
\]

where in the second inequality we have used the fact that \( P_{\text{row}}u^{(n)} \) is an orthogonal projector, hence \( \|P_{\text{row}}u^{(n)}\|_F = \sqrt{R} \). Finally,

\[
\sup_{0 \leq t \leq \delta} \|U_t^{(n+1)} - \varphi\|_F \leq 4\gamma(3\rho^2 + 1)C_{\text{Lip}}(1 + 3R(3\rho^2 + 1))(\sqrt{d} + \sqrt{R})^2 \delta \leq \eta^2.
\]

Thus, by induction we conclude \( (U^{(n)}, Y^{(n)}) \in \mathbb{D}_{\text{det}} \times \mathbb{D}_{\text{sto}} \) for \( n \in \mathbb{N} \). \( \square \)

We now establish a Lipschitz continuity for \( F_1 \) and \( F_2 \) on \( \mathbb{D}_{\text{det}} \times \mathbb{D}_{\text{sto}} \).

**Lemma 3.2.** Take \( \delta > 0 \) as in (3.3). There exists a constant \( \tilde{C} := \tilde{C}_{a,b,R,\rho,\delta,\gamma} > 0 \) such that for any \( (V,Z), (\tilde{V},\tilde{Z}) \in \mathbb{D}_{\text{det}} \times \mathbb{D}_{\text{sto}} \) it holds

\[
\sup_{t \in [0,\delta]} \|F_1(V,Z)(t) - F_1(\tilde{V},\tilde{Z})(t)\|^2 + \mathbb{E}\left[ \sup_{t \in [0,\delta]} |F_2(V,Z)(t) - F_2(\tilde{V},\tilde{Z})(t)|^2 \right] \\
\leq \tilde{C}\int_0^\delta \left( \sup_{t \in [0,s]} \|V_t - \tilde{V}_t\|_F^2 + \mathbb{E}\left[ \sup_{t \in [0,s]} |Z_t - \tilde{Z}_t|^2 \right] \right) ds \tag{3.4}
\]

**Proof.** For any \( (V,Z), (\tilde{V},\tilde{Z}) \in \mathbb{D}_{\text{det}} \times \mathbb{D}_{\text{sto}} \), from Doob’s martingale inequality and Itô’s isometry we have

\[
\mathbb{E}\left[ \sup_{t \in [0,\delta]} |F_2(V,Z)(t) - F_2(\tilde{V},\tilde{Z})(t)|^2 \right] \\
\leq 2\mathbb{E}\left[ \sup_{t \in [0,\delta]} |\int_0^t V_s a(s,V_s^\top Z_s) ds - \int_0^t \tilde{V}_s a(s,\tilde{V}_s^\top \tilde{Z}_s) ds|^2 \right] \\
+ 2\mathbb{E}\left[ \sup_{t \in [0,\delta]} \left( \int_0^t (V_s b(s,V_s^\top Z_s) + \tilde{V}_s b(s,\tilde{V}_s^\top \tilde{Z}_s))dW_s \right)^2 \right] \\
\leq 2\mathbb{E}\left[ \sup_{t \in [0,\delta]} \int_0^t |V_s a(s,V_s^\top Z_s) - \tilde{V}_s a(s,\tilde{V}_s^\top \tilde{Z}_s)|^2 ds \right] \\
+ 8\mathbb{E}\left[ \int_0^\delta \|V_s b(s,V_s^\top Z_s) - \tilde{V}_s b(s,\tilde{V}_s^\top \tilde{Z}_s)\|_F^2 ds \right] \\
\leq C_{a,b,R,\rho,\delta}\int_0^\delta \left( \sup_{s \in [0,\delta]} \|V_s - \tilde{V}_s\|_F^2 + \mathbb{E}\left[ |Z_s - \tilde{Z}_s|^2 \right] \right) ds \\
\leq C_{a,b,R,\rho,\delta}\int_0^\delta \left( \sup_{r \in [0,\delta]} \|V_r - \tilde{V}_r\|_F^2 + \mathbb{E}\left[ \sup_{r \in [0,\delta]} |Z_r - \tilde{Z}_r|^2 \right] \right) ds,
\]
where $C_{a,b,R,p,\delta}$ is a positive constant. Similarly, we have for a constant $C_{a,b,R,p,\delta,\gamma} > 0$ that
\[
\sup_{t \in [0,\delta]} \| F_1(V, Z)(t) - F_1(\bar{V}, \bar{Z})(t) \|_2^2 \leq C_{a,b,R,p,\delta,\gamma} \int_0^\delta \left( \sup_{r \in [0,s]} \| V_r - \bar{V}_r \|_F^2 + \mathbb{E} \left[ \sup_{r \in [0,s]} \| Z_r - \bar{Z}_r \|_2^2 \right] \right) ds,
\]
where we used the Lipschitz continuity of $C_{Y}^{-1}$ and $P_{U,\cdot}$; see [14, Lemma 3.5] and Lemma A.3. □

Thanks to the previous results, we have that sequences $(U^{(n)})_n$ and $(Y^{(n)})_n$ not only live in $\mathbb{D}_{\text{det}}$ and $\mathbb{D}_{\text{sto}}$, respectively, but also converge therein.

Lemma 3.3. The sequence $(U^{(n)})_n$ admits a limit $U \in \mathbb{D}_{\text{det}} \subset C([0,\delta]; \mathbb{R}^{R \times d})$, and the sequence $(Y^{(n)})_n$ admits a limit $Y \in \mathbb{D}_{\text{sto}} \subset C([0,\delta]; \mathbb{R}^R)$ almost surely. Moreover, $Y$ is also an $L^2(\Omega; C([0,\delta]; \mathbb{R}^R))$-limit.

Proof. From Lemma 3.1 we have $(U^{(n)}, Y^{(n)}) \in \mathbb{D}_{\text{det}} \times \mathbb{D}_{\text{sto}}$ for all $n \in \mathbb{N}$. Let $\Delta^{(n)}_U(s) := \sup_{0 \leq r \leq s} \| U^{(n)}(r) - U^{(n-1)}(r) \|_F^2$. Then, since $\| U^{(n)} - U^{(n-1)} \|_F^2$ is continuous on $[0,\delta]$, so is $\Delta^{(n)}_U$, and thus $\Delta^{(n)}_U$ is measurable. Similarly, $\Delta^{(n)}_Y(s) := \sup_{0 \leq r \leq s} \| Y^{(n)}(r) - Y^{(n-1)}(r) \|_F^2$ is a.s. continuous on $[0,\delta]$.

Noting that $Y^{(n)} \in \mathbb{D}_{\text{sto}}$ implies $\| C_{Y}^{-1}Y^{(n)} \|_F^2 \leq 2\gamma$, from Lemma 3.2 we have
\[
\Delta^{(n)}_U(\delta) + \mathbb{E}[\Delta^{(n)}_U(\delta)] \leq \tilde{C} \int_0^{\delta} \left( \Delta^{(n-1)}_U(s) + \mathbb{E}[\Delta^{(n-1)}_U(s)] \right) ds
\leq \tilde{C} \int_0^{\delta} \int_0^{s_{n-1}} \cdots \int_0^{s_1} \left( \Delta^{(1)}_U(s_1) + \mathbb{E}[\Delta^{(1)}_U(s_1)] \right) ds_1 \cdots ds_{n-1}
= \left( \frac{\tilde{C} \delta}{(n-1)!} \right)^n (\Delta^{(1)}_U(\delta) + \mathbb{E}[\Delta^{(1)}_U(\delta)]).
\] (3.5)

Chebyshev's inequality then implies
\[
\sum_{n=1}^{\infty} \mathbb{P}\left( \Delta^{(n)}_U(\delta) + \Delta^{(n)}_Y(\delta) \geq \frac{1}{2\gamma} \right) \leq \left( \frac{\Delta^{(1)}_U(\delta) + \mathbb{E}[\Delta^{(1)}_U(\delta)]}{(n-1)!} \right)^n (2\tilde{C} \delta)^n < \infty,
\]
and thus from the Borel-Cantelli lemma we have
\[
\mathbb{P}\left( \left\{ k = k(\omega) \text{ s.t. } n \geq k \implies \Delta^{(n)}_U(\delta) + \Delta^{(n)}_Y(\delta) < \frac{1}{2\gamma} \right\} \right) = 1.
\]

Hence, $(Y^{(n)}(\omega))_n$ has a limit $Y(\omega) \in C([0,\delta]; \mathbb{R}^R)$, where the convergence is uniformly in $t$ on $[0,\delta]$, a.s. Moreover, from the completeness of the underlying probability space, $Y$ is $(\mathcal{F}_t)$-adapted. Also, from $Y^{(n)} \in \mathbb{D}_{\text{sto}}$, $n \in \mathbb{N}$, Fatou’s lemma implies
\[
\mathbb{E}\left[ \sup_{0 \leq s \leq \delta} |Y_t| \right] \leq \liminf_{n \to \infty} \mathbb{E}\left[ \sup_{0 \leq s \leq \delta} |Y^{(n)}_t| \right] \leq 4\rho, \tag{3.6}
\]
\[
\mathbb{E}\left[ \sup_{0 \leq s \leq \delta} |Y_t - \xi| \right] \leq \eta^2, \tag{3.7}
\]
and thus $Y \in \mathbb{D}_{\text{sto}}$. An analogous argument applies to see that $(U^{(n)})_n$ has a limit $U$ in $C([0,\delta]; \mathbb{R}^{R \times d})$ with $U \in \mathbb{D}_{\text{det}}$.

The sequences $Y^{(n)}$ converge in $L^2(\Omega; C([0,\delta]; \mathbb{R}^R))$ as well. Indeed, from (3.5), for $j > n$ we have
\[
\sqrt{\mathbb{E}\left[ \sup_{0 \leq s \leq \delta} |Y^{(j)}_t - Y^{(n)}_t| \right]^2} \leq \sum_{k=n}^{j-1} \sqrt{\mathbb{E}\left[ \sup_{0 \leq s \leq \delta} |Y^{(k+1)}_t - Y^{(k)}_t| \right]^2}
\leq \sqrt{\Delta^{(1)}_U(\delta) + \mathbb{E}[\Delta^{(1)}_U(\delta)]} \sum_{k=n}^{j-1} \frac{(\tilde{C} \delta)^{k-1}}{(k-1)!}.
\]
and thus Fatou’s lemma implies

\[ \mathbb{E} \left[ \sup_{0 \leq t \leq s} |Y_t - Y_t^{(n)}|^2 \right] \leq (\Delta_U^{(1)}(\delta) + \mathbb{E}[\Delta_U^{(1)}(\delta)]) \left( \sum_{k=n}^{\infty} \sqrt{\frac{(C\delta)^{k-1}}{(k-1)!}} \right)^2 < \infty, \]

hence \( \lim_{n \to \infty} \mathbb{E} \left[ \sup_{0 \leq t \leq s} |Y_t - Y_t^{(n)}|^2 \right] = 0. \)

We are now ready to establish an existence result for the DO solution.

**Theorem 3.4 (Existence of a DO solution).** For any \((U_0, Y_0)\), with \(\|Y_0\|_{L^2(\Omega)} = \rho > 0\) and \(\|C_{Y_0}\|_F = \gamma > 0\) the DO equations (2.6) and (2.7) have a local (in time) strong DO solution \((U, Y) \in \mathbb{D}_{\text{det}} \times \mathbb{D}_{\text{sto}}\) with \(\delta\) given by (3.3).

**Proof.** We show that the limit \((U, Y)\) in Lemma 3.3 satisfies \(U = F_1(U, Y)\) and \(Y = F_2(U, Y)\), hence it is a DO solution. From Lemma 3.2, \(F_1\) and \(F_2\) are (Lipschitz) continuous on \(\mathbb{D}_{\text{det}} \times \mathbb{D}_{\text{sto}}\):

\[
\max \left\{ \sup_{t \in [0, \delta]} \|F_1(V, Z)(t) - F_1(V, Z)(t)\|_F^2, \mathbb{E} \left[ \sup_{t \in [0, \delta]} |F_2(V, Z)(t) - F_2(V, Z)(t)|^2 \right] \right\} \\
\leq \tilde{C} \int_0^\delta \left( \sup_{t \in [0, s]} \|V_t - \tilde{V}_t\|_F^2 + \mathbb{E} \left[ \sup_{t \in [0, s]} |Z_t - \tilde{Z}_t|^2 \right] \right) ds \\
\leq \tilde{C} \delta \left( \sup_{t \in [0, \delta]} \|V_t - \tilde{V}_t\|_F^2 + \mathbb{E} \left[ \sup_{t \in [0, \delta]} |Z_t - \tilde{Z}_t|^2 \right] \right).
\]

Thus, we have

\[
\mathbb{E} \left[ \sup_{t \in [0, \delta]} |Y_t - F_2(U, Y)(t)|^2 \right] = \lim_{n \to \infty} \mathbb{E} \left[ \sup_{t \in [0, \delta]} |Y_t^{(n)} - F_2(U^{(n)}, Y^{(n)})(t)|^2 \right] \\
= \lim_{n \to \infty} \mathbb{E} \left[ \sup_{t \in [0, \delta]} |Y_t^{(n)} - Y_t^{(n+1)}|^2 \right] = 0,
\]

and hence \(Y_t = F_2(U, Y)(t)\) for \(t \in [0, \delta]\), a.s. We see \(U_t = F_1(U, Y)(t)\) analogously.

To establish uniqueness, first we will show the following norm bound analogous to Lemma 2.6.

**Lemma 3.5.** For \(T > 0\), suppose that \(U \in C([0, T]; \mathbb{R}^{R \times d})\), with \(U_0\) having orthonormal rows, and \(Y \in L^2(\Omega; C([0, T]; \mathbb{R}^R))\), with \(Y_0\) having linearly independent components, satisfy \(U_t = F_1(U, Y)(t)\) and \(Y_t = F_2(U, Y)(t)\) for all \(t \in [0, T]\). Then, for all \(t \in [0, T]\) we have

\[
\|U_t\|_F = \sqrt{R}; \quad \mathbb{E}[|Y_1|^2] \leq 3(\mathbb{E}[|Y_0|^2] + (1 + T)TC_{lb}) \exp(3(1 + T)TC_{lb}) =: M(T).
\]

**Proof.** First, from \(U_t = F_1(U, Y)(t)\), the function \(U\) is absolutely continuous on \([0, T]\), and thus differentiable almost everywhere. The derivative \(\dot{U}_t\) satisfies

\[
\dot{U}_t U_t^\top = C_{Y_1}^{-1} \mathbb{E}[Y_{1a}(t, U_t^\top Y)^\top ](I_{d \times d} - P_{U_t^\top}) U_t^\top = 0,
\]

and thus \(\frac{d}{dt}(U_t U_t^\top) = 0\) a.e. on \([0, T]\). Therefore, from the orthonormality of the initial condition \(\varphi \varphi^\top = I_{R \times R}\), for all \(t \in [0, T]\) we have

\[
(U_t U_t^\top)_{jk} = \epsilon_{jk} + \int_0^t 0 \, ds = \epsilon_{jk},
\]

where \(\epsilon_{jk} = 1\) only if \(j = k\), and 0 otherwise. This shows the identity (3.8).
For $Y$, Itô’s isometry implies
\[
\mathbb{E}[|Y_t|^2] \leq 3\mathbb{E}[|Y_0|^2 + \int_0^t \|U_s\|^2 \sigma(s, Y_s)^2 \, ds] + 3\mathbb{E}\left[\int_0^t \|U_s b(s, Y_s)\|^2 \, ds\right]
\]
\[
\leq 3\mathbb{E}[|Y_0|^2] + 3(1 + T)C_{\text{gb}} \int_0^t (1 + \mathbb{E}[|Y_s|^2]) \, ds,
\]
where we used Assumption 2 $|a(s, x)|^2 + \|b(s, x)\|^2 \leq C_{\text{gb}}(1 + |x|^2)$. Thus, Gronwall’s lemma implies (3.9).

Now the following uniqueness result follows.

**Theorem 3.6 (Uniqueness of DO solutions).** Let the assumptions of Lemma 3.5 hold. For $T > 0$, suppose that $U, \tilde{U} \in C([0, T]; \mathbb{R}^{d \times d})$ and $Y, \tilde{Y} \in L^2(\Omega; C([0, T]; \mathbb{R}^d))$ satisfy $U_t = F_1(U, Y)(t)$ and $\tilde{U}_t = F_1(\tilde{U}, \tilde{Y})(t)$; $Y_t = F_2(U, Y)(t)$ and $\tilde{Y}_t = F_2(\tilde{U}, \tilde{Y})(t)$ for $t \in [0, T]$. Then, we have
\[
\mathbb{P}\left(\sup_{0 \leq t \leq T} \|U_t - \tilde{U}_t\|_F^2 + \sup_{0 \leq t \leq T} \|Y_t - \tilde{Y}_t\| > 0\right) = 0.
\]

**Proof.** By hypothesis, the solutions $U, \tilde{U}$ and $Y, \tilde{Y}$ satisfy the stability estimates shown in Lemma 3.5. Moreover, from the continuity of $t \to \mathbb{E}[|Y_t Y_t^\top|^{-1}]^{-1}$, we have
\[
\max \left\{ \sup_{s \in [0, T]} \mathbb{E}[|Y_s Y_s^\top|^{-1}]^{-1}, \sup_{s \in [0, T]} \mathbb{E}[|\tilde{Y}_s \tilde{Y}_s^\top|^{-1}]^{-1} \right\} = \tilde{\gamma} < \infty
\]
for some $\tilde{\gamma} > 0$. Then, noting the norm bounds (3.8) and (3.9), by an argument similar to the proof of Lemma 3.2 (see also [14, Lemma 3.5] and Lemma A.3), with a constant $\tilde{C} = \tilde{C}(\tilde{\gamma}) > 0$ we have
\[
\sup_{0 \leq s \leq t} \|U_s - U'_s\|_F^2 + \mathbb{E}\left[\sup_{0 \leq s \leq t} |Y_s - Y'_s|^2\right] \leq \tilde{C} \int_0^t \left( \sup_{0 \leq s \leq r} \|U_s - U'_s\|_F^2 + \mathbb{E}\left[\sup_{0 \leq s \leq r} |Y_s - Y'_s|^2\right] \right) \, dr
\]
(3.10)
for $t \in [0, T]$. Thus, applying the Gronwall’s lemma yields
\[
\sup_{0 \leq s \leq t} \|U_s - U'_s\|_F^2 + \mathbb{E}\left[\sup_{0 \leq s \leq t} |Y_s - Y'_s|^2\right] = 0.
\]
Now the proof is complete. \qed

**Remark 3.7.** The uniqueness of the DO solution can be also deduced from the proof of Proposition 2.9. To see this, let $(U, Y)$ and $(\tilde{U}, \tilde{Y})$ be two strong DO solutions with the same initial datum $(U_0, Y_0)$. Then, following the proof of Proposition 2.9, we have $(U, Y) = (\Theta U_t, \Theta Y_t)$ with $\Theta = I_{R \times R}$.

We conclude this section by showing the continuity of the solution with respect to the initial datum.

**Lemma 3.8.** Let us consider two DO solutions $(U_t, Y_t)$, $(\tilde{U}_t, \tilde{Y}_t)$ on $[0, T]$ with initial data $(U_0, Y_0)$, $(\tilde{U}_0, \tilde{Y}_0)$, respectively. Then, under Assumptions 1 and 2,
\[
\mathbb{E}\left[\sup_{t \in [0, T]} |Y_t - \tilde{Y}_t|^2\right] + \mathbb{E}\left[\sup_{t \in [0, T]} |U_t - \tilde{U}_t|^2\right] \leq C_{a, b, R, \rho, T, \gamma} \left( \mathbb{E}[|Y_0 - \tilde{Y}_0|^2] + \|U_0 - \tilde{U}_0\|^2 \right)
\]
holds. Moreover, consider $X_t$ and $\tilde{X}_t$ be the DO approximations with initial data $X_0$ and $\tilde{X}_0$ defined on $[0, T]$, and denote
\[
\gamma := \inf_{t \in [0, T]} \sigma_R(\mathbb{E}[|X_t X_t^\top|]),
\]

16
where \( \sigma_R(A) \) is the smallest singular value of a rank-\( R \) matrix \( A \in \mathbb{R}^{R \times R} \). If \( \mathbb{E}[\|X_0 - \tilde{X}_0\|^2] < \left( \frac{\gamma}{2R} \right)^2 \), then, for every \( \tilde{T} > 0 \) such that

\[
(T + 1) [C_{\text{lb}}(1 + M(T)) + 2C_{\text{Lip}} M(T)] \tilde{T} \leq \left( \frac{\gamma}{2R} \right)^2 .
\]

there exists a positive constant \( C > 0 \) satisfying

\[
\sup_{t \in [0, \tilde{T}]} \mathbb{E}[\|X_t - \tilde{X}_t\|^2] \leq C \mathbb{E}[\|X_0 - \tilde{X}_0\|^2]. \tag{3.11}
\]

**Proof.** Following an argument similar to the proof of Lemma 3.2 and Lipschitz continuity result of Lemma A.3, for the stochastic basis it holds

\[
\mathbb{E}[\sup_{t \in [0,T]} |Y_t - \tilde{Y}_t|^2] \leq 2\mathbb{E}[|Y_0 - \tilde{Y}_0|^2] + C_{a,b,R,T} \int_0^T (\sup_{r \in [0,t]} \|U_r - \tilde{U}_r\|_F^2 + \mathbb{E}[\sup_{r \in [0,t]} |Y_r - \tilde{Y}_r|^2])dt,
\]

and, similarly, noting the Lipschitz continuity of the inverse Gram matrix [14, Lemma 3.5], for the deterministic basis we have

\[
\|U_t - \tilde{U}_t\|_F^2 \leq 2\|U_0 - \tilde{U}_0\|_F^2 + C_{a,b,R,T} \int_0^T (\sup_{r \in [0,t]} \|U_r - \tilde{U}_r\|_F^2 + \mathbb{E}[\sup_{r \in [0,t]} |Y_r - \tilde{Y}_r|^2])dt.
\]

Then, the Gronwall’s lemma yields the first part of statement. Finally, to prove (3.11), we proceed as above and as done in Theorem 2.7. Via triangular inequality, one gets

\[
\sqrt{\mathbb{E}[\|X_{\tilde{T}} - \tilde{X}_{\tilde{T}}\|^2]} \leq \sqrt{\mathbb{E}[\|X_0 - \tilde{X}_0\|^2]} + \sqrt{(T + 1) [C_{\text{lb}}(1 + M(T)) + 2C_{\text{Lip}} M(T)] \tilde{T}}
\]

\[
< \frac{\gamma}{2R} + \frac{\gamma}{2R} - \frac{\gamma}{R} \tag{3.12}
\]

and, hence, Lemma A.2 holds. Therefore, for all \( t \in [0, \tilde{T}] \) we have for a positive constant \( C \) such that it holds

\[
\mathbb{E}[\|X_t - \tilde{X}_t\|^2] \leq 2\mathbb{E}[\|X_0 - \tilde{X}_0\|^2] + 2\mathbb{E}[\|Y_t\|^2] \int_0^t \mathbb{E}[\|X_s - \tilde{X}_s\|^2]ds,
\]

\[
\leq C \mathbb{E}[\|X_0 - \tilde{X}_0\|^2],
\]

where in the last line we use the Gronwall’s lemma.

4 Maximality

In the previous section, we established the existence and uniqueness of strong DO solutions locally in time on an interval \([0, T]\). In this section, we investigate how much such an interval can be extended.

We give a characterisation of the maximal interval of existence of the strong DO solution in terms of \( \|C_{\text{Y}}^{-1}\|_F \). It turns out that the DO solution can be extended until \( \|C_{\text{Y}}^{-1}\|_F \) explodes. If \( \|C_{\text{Y}}^{-1}\|_F \) stays bounded for all \( t > 0 \), then the DO solution exists globally. If \( \|C_{\text{Y}}^{-1}\|_F \) explodes at a finite explosion time \( T_e \), the couple \((U, Y)\) inevitably ceases to exist at \( T_e \); we will show nevertheless that the DO approximation \( X = U^\top Y \) can be extended beyond \( T_e \).

4.1 Explosion time of the DO solution

Theorem 3.4 guarantees the (unique) existence of a strong DO solution, albeit up to possibly a short time \( T \). In this section, we show that the solution can be extended until \( C_{\text{Y}}^{-1} \) becomes singular.
Analogous maximality results have been considered in the DLRA literature for deterministic and random PDEs [19, 14]. For the SDE case of this paper, we need to proceed with caution. Indeed, adhering to the definition of SDEs, we need the DO solution to be path-wise continuous a.s. As such, we consider extension with countable number of operations, which we describe in the following.

Let $[0, T]$ be the interval on which the DO solution $(U, Y)$ exists; such existence is guaranteed by Theorem 3.4. Let us choose $n \in \mathbb{N}$ such that the following two bounds are satisfied

\[ E[\|Y_T\|^2] \leq E[\|Y_0\|^2] + n := \rho_n^2; \]
\[ \|C_{Y_t}^{-1}\|_F^2 \leq \|C_{Y_t}^{-1}\|_\infty^2 + n := \gamma_n^2. \]

We will show that the solution can be extended at least until $E[\|Y_T\|^2]$ or $\|C_{Y_T}^{-1}\|_\infty^2$ hits the bound $\rho_n^2$ or $\gamma_n^2$. Define $\delta(n)$ by

\[ \delta(n) := \min \left\{ 1, \frac{\min \{ 1, \eta_n^2 \}}{36RC_{\text{gh}}(1 + 3R(3\rho_n^2 + 1))}, \frac{\min \{ \eta_n^2, R \}}{8\gamma_n^2(3\rho_n^2 + 1)C_{\text{gh}}(1 + 3R(3\rho_n^2 + 1))(\sqrt{d} + \sqrt{R})^2} \right\}, \]

where $\eta_n := \min \{ \eta(\rho_n, \gamma_n), \eta(\sqrt{R}, \sqrt{R}) \}$, with $\eta(\cdot, \cdot)$ defined in (A.1). Then from the proofs of Lemmata 3.1 and 3.3, and Theorem 3.4, we can construct a convergent Picard-iteration for the $\eta$-sequence, which allows us to define

\[ \text{Lemma 3.1 and 3.3, and Theorem 3.4, let us choose} \]

\[ \text{extension with countable number of operations, which we describe in} \]

\[ \text{the following.} \]

\[ \text{As such, we consider extension with countable number of operations, which we describe in} \]

\[ \text{the following.} \]

\[ \text{From the argument above, the following quantities are well defined for any} \]

\[ \text{any} \]

\[ \text{with a convention inf} \varnothing = \infty. \text{ With these, we define the sequence} \]

\[ \text{which is a sequence of stopping times. By continuity of the paths,} (\tau_n)_{n \in \mathbb{N}} \text{ is a non-decreasing} \]

\[ \text{sequence, which allows us to define} \]

\[ \text{now we will show that if} \]

\[ \text{then the norm of the inverse of the Gram matrix must} \]

\[ \text{Proposition 4.1. We have either} \]

\[ \text{If} \]

\[ \text{Proof. From the norm bound (3.9), for sufficiently large} \]

\[ \text{we have} \]

\[ \text{We will first show that} \]

\[ \text{and assume} \]

\[ \text{and} \]

\[ \text{Then, we have} \]

\[ \text{But then since} \]

\[ \text{Proof. From the norm bound (3.9), for sufficiently large} \]

\[ \text{we have} \]

\[ \text{We will first show that} \]

\[ \text{and assume} \]

\[ \text{Then, we have} \]

\[ \text{But then since} \]

\[ \text{Thus for any} \]

\[ \text{which is absurd. Hence,} \]

\[ \text{Proposition 4.1. We have either} \]

\[ \text{If} \]

\[ \text{Proof. From the norm bound (3.9), for sufficiently large} \]

\[ \text{we have} \]

\[ \text{We will first show that} \]

\[ \text{and assume} \]

\[ \text{Then, we have} \]

\[ \text{But then since} \]

\[ \text{Thus for any} \]

\[ \text{which is absurd. Hence,} \]
To conclude the proof we will show
\[ \lim_{t \uparrow T_e} \|C_{Y_t}^{-1}\|_F = \infty. \]
If this is false, then there exist a sequence \( t_m \uparrow T_e \) and \( \gamma > 0 \) such that \( \|C_{Y_{t_m}}^{-1}\|_F \leq \gamma \) for all \( m \geq 0 \). But since \( \limsup_{t \uparrow T_e} \|C_{Y_t}^{-1}\|_F = \infty \) there is a sequence \( s_k \uparrow e \) such that \( \|C_{Y_s}^{-1}\|_F \geq \gamma + 1 \) for all \( k \geq 0 \). We take a subsequence \( (s_{k_m})_m \) so that \( t_m < s_{k_m} \) for all \( m \). From the continuity of \( t \mapsto \|C_{Y_t}^{-1}\|_F \) on \([t_m, s_{k_m}]\), there exists \( h_m \in [0, s_{k_m} - t_m] \) such that \( \|C_{Y_{t_m+h_m}}^{-1}\|_F = \gamma + 1 \). Now, from (3.9) and [14, Lemma 3.5] we have for any \( m \geq 0 \)
\[ 1 \leq \|C_{Y_{t_m+h_m}}^{-1}\|_F - \|C_{Y_{t_m}}^{-1}\|_F \leq C_{T_e, R, \gamma} \|Y_{t_m+h_m} - Y_{t_m}\|_{L^2(\Omega)^n}, \]
which is absurd since \( h_m \to 0 \) as \( m \to \infty \) and \( Y \) is continuous on \([0, T_e]\). Hence, the proof is complete. \( \square \)

4.2 Extension up to the explosion time

Even when the explosion time \( T_e \) for the DO solution is finite, and thus \( U \) and \( Y \) cease to exist at \( T_e \), we will show that the product \( X = U^\top Y \) nevertheless admits a continuous extension up to \([0, T_e]\), and beyond \( T_e \), under suitable assumptions.

For any \( t' < T_e \), from (2.17) we have
\[
X_t - X_{t'} = \int_{t'}^t (\mathcal{P}_{U(X_s)} + \mathcal{P}_{Y(X_s)}) a(s, X_s) \, ds + \int_{t'}^t \mathcal{P}_{U(X_s)} b(s, X_s) \, dW_s,
\]
and, hence, the Itô’s isometry implies
\[
\mathbb{E}[|X_t - X_{t'}|^2] \leq 2T_e \int_{t'}^t |a(s, X_s)|^2 \, ds + 2 \int_{t'}^t \|b(s, X_s)\|^2 \, ds.
\]
From Assumption 2, the orthogonality of \( U_t \) and the norm bound (3.9) of \( Y_t \) it follows that
\[
\mathbb{E}[|X_t - X_{t'}|^2] \leq C(t - t')
\]
with \( C := 4 \max\{1, T_e\} C_{gb}(1 + M(T_e)) \). Therefore, \( (X_t)_{0 \leq t < T_e} \) admits a unique extension \( X_{T_e} := \lim_{t \uparrow T_e} X_t \in L^2(\Omega; \mathbb{R}^d) \).

Thus obtained \( (X_t)_{0 \leq t < T_e} \) is continuous from \([0, T_e]\) to \( L^2(\Omega; \mathbb{R}^d) \), but not necessarily pathwise a.s. continuous on \([0, T_e]\). It turns out that for initial data with suitable integrability, the DO approximation \( X_t \) actually admits a.s. H"older continuous paths. Namely, we assume the following \( P \)-integrability condition.

**Assumption 4.** The initial condition \( X_0 \) satisfies
\[
\mathbb{E}[|X_0|^{2k}] < +\infty, \quad \text{for some } k \in \mathbb{N}.
\] (4.5)
Notice that this condition is equivalent to
\[
\mathbb{E}[|Y_0|^{2k}] < \infty, \quad \text{for some } k \in \mathbb{N},
\] (4.6)
where \( Y_0 \in [L^2(\Omega)]^R \) is arbitrary such that \( X_0 = U_0^\top Y_0 \) for \( U_0 \in \mathbb{R}^{R \times d} \) orthonormal. Indeed, for any DO initial condition \( U_0^\top Y_0 = X_0 \), the orthogonality of \( U_0 \) implies
\[
\mathbb{E}[|Y_0|^{2k}] \leq \mathbb{E}\left[ \left( \|U_0^\top Y_0\|_2^2 \right)^k \right] \leq \mathbb{E}[|X_0|^{2k}] \leq \mathbb{E}\left[ \left( \|U_0^\top Y_0\|_2^2 \right)^k \right] = \mathbb{E}[|Y_0|^{2k}] < +\infty.
\]
provided that the $2k$-th moment of either $Y_0$ or $X_0$ (hence both) exists. Thus, $\mathbb{E}[|X_0|^{2k}] = \mathbb{E}[|Y_0|^{2k}]$. Similarly, for any other DO initial condition $\hat{Y}_0$ we have

$$\mathbb{E}[|\hat{Y}_0|^{2k}] = \mathbb{E}[|X_0|^{2k}] = \mathbb{E}[|Y_0|^{2k}] .$$

Hence, Assumption 4 is equivalent to (4.6), with an arbitrarily fixed stochastic basis.

Analogously, for all $t > 0$ we have

$$\mathbb{E}[|X_t|^{2k}] = \mathbb{E}[|Y_t|^{2k}] < +\infty .$$

(4.7)

The DO solution preserves the $\mathbb{P}$-integrability of the initial datum.

**Lemma 4.2** (Even order moments of the solution). Let $a$ and $b$ satisfy Assumptions 1 and 2. Suppose that the DO solution for (2.1) exists on $[0,T]$. Suppose that Assumption 4 is fulfilled for some $k \in \mathbb{N}$. Then, for any $t \in [0,T]$ we have

$$\mathbb{E}[|Y_t|^{2k}] \leq (\mathbb{E}[|Y_0|^{2k}] + K_1(T))K_2(T) ,$$

with $K_1(T) := (3k^2 \frac{C_l a b T}{(1+1/C_l a b)^{-r}})$ and $K_2(T) := \exp\{6k^2 C_l a b (1 + 1/C_l a b) T\}$.

**Proof.** From the Itô formula, $|Y_t|^{2k}$ satisfies the following SDE (see also [17, Theorem 4.5.4]):

$$|Y_t|^{2k} = |Y_0|^{2k} + \int_0^t 2k|Y_s|^{2k-2} \left( U_s a(s, U_s^T Y_s) \right)^T Y_s +$$

$$+ k|Y_s|^{2k-2} \text{Tr} \left( U_s b(s, U_s^T Y_s) \right) \left( U_s b(s, U_s^T Y_s) \right)^T Y_s +$$

$$+ k(2k-1)|Y_s|^{2k-4} |Y_s^T U_s b(s, U_s^T Y_s)|^2 ds +$$

$$+ \int_0^t 2k|Y_s|^{2k-2} (Y_s)^T U_s b(s, U_s^T Y_s) dW_s .$$

We take the expectation of both sides, and, noting the progressive measurability of $Y_t$,
Gronwall’s lemma: Then, by using the relation \((1 + r^2)^{2k-2} \leq 1 + 2r^{2k}\) for \(r \in \mathbb{R}_+\), the statement follows by Gronwall’s lemma:

\[
\mathbb{E}[|Y_t|^{2k}] \leq \mathbb{E}[|Y_0|^{2k}] + 3k^2 \frac{C_{\text{lb}}}{(1 + 1/C_{\text{lb}})^{2k-2}} \int_0^t \mathbb{E}[1 + 2(\sqrt{1 + 1/C_{\text{lb}}})^{2k}|Y_s|^{2k}]ds
\]

\[
\leq \mathbb{E}[|Y_0|^{2k}] + 3k^2 \frac{C_{\text{lb}}}{(1 + 1/C_{\text{lb}})^{2k-2}} T + 6k^2C_{\text{lb}}(1 + 1/C_{\text{lb}}) \int_0^t \mathbb{E}[|Y_s|^{2k}]ds
\]

With Lemma 4.2, we can now establish a “Hölder” type bound on \(\mathbb{E}[|X_t - X_{t'}|^{2k}]\) for \(0 \leq t < t' < T_e\), which by Kolmogorov-Chentsov theorem, implies the existence of an a.s. continuous version of \(X_t\).

**Proposition 4.3.** Suppose that the DO approximation \(X_t\) of (2.1) exists on \([0, T_e]\). Suppose that Assumption 4 holds for some \(k \in \mathbb{N}\). If \(a\) and \(b\) satisfy Assumption 2, then there exists a constant \(C := C(X_0, R, k, T_e, C_{\text{lb}}) > 0\) such that

\[
\mathbb{E}[|X_t - X_{t'}|^{2k}] \leq C(t - t')^k, \quad 0 \leq t' < t < T_e. \tag{4.8}
\]

**Proof.** The proof follows closely the one in [17, Theorem 4.5.4]. First, notice that, in the view of (4.7), Lemma 4.2 gives an estimate of the 2k-moments of the DO approximation \(X\) for some \(k \in \mathbb{N}\). Now we use the inequality \(|r_1 + \cdots + r_m|^p \leq m^{p-1} \sum_{i=1}^m |r_i|^p\) for \(r \in \mathbb{R}\) twice and Jensen’s
inequality to (4.4) to obtain
\[
\mathbb{E}[|X_t - X_{t'}|^{2k}] = \mathbb{E}[\int_{t'}^t (\mathcal{P}_{t}(X_s) + \mathcal{P}_{X_s} - \mathcal{P}_{t}(X_s) \mathcal{P}_{X_s}) a(s, X_s) \, ds \\
+ \int_{t'}^t \mathcal{P}_{t}(X_s) b(s, X_s) dW_s |^{2k}]
\]
\[
\leq 2^{2k-1} \mathbb{E}[\int_{t'}^t (\mathcal{P}_{t}(X_s) + \mathcal{P}_{X_s} - \mathcal{P}_{t}(X_s) \mathcal{P}_{X_s}) a(s, X_s) \, ds]^{2k} \\
+ 2^{2k-1} \mathbb{E}[\int_{t'}^t \mathcal{P}_{t}(X_s) b(s, X_s) dW_s |^{2k}]
\]
\[
\leq 2^{2k-1} (t-t')^{2^{k-1}} \mathbb{E}[\int_{t'}^t (\mathcal{P}_{t}(X_s) + \mathcal{P}_{X_s} - \mathcal{P}_{t}(X_s) \mathcal{P}_{X_s}) |^2 a(s, X_s) |^2 \, ds] \\
+ 2^{2k-1} \mathbb{E}[\int_{t'}^t \mathcal{P}_{t}(X_s) b(s, X_s) dW_s |^{2k}]
\]
\[
\leq 2^{2k-1} (t-t')^{2^{k-1}} \mathbb{E}[\int_{t'}^t |a(s, X_s)|^{2k} \, ds] + 2^{2k-1} \mathbb{E}[\int_{t'}^t \mathcal{P}_{t}(X_s) b(s, X_s) dW_s |^{2k}]
\]

For the first term in the last inequality above, using the inequality \((1 + r^2)^k \leq 2^{k-1} (1 + r^{2k})\) for \(r \in \mathbb{R}_+\), Assumption 2 and Lemma 4.2, we get
\[
\mathbb{E}[\int_{t'}^t |a(s, X_s)|^{2k} \, ds] \leq \mathbb{E}[\int_{t'}^t C_{lgb} |1 + |X_s|^2|^{k} \, ds] \\
\leq C_{lgb} 2^{k-1} \int_{t'}^t (1 + \mathbb{E}[|U_s Y_s|^{2k}]) \, ds \\
\leq C_{lgb} 2^{k-1} \int_{t'}^t (1 + \mathbb{E}[|Y_s|^{2k}]) \, ds \\
\leq C_{lgb} 2^{k-1} \int_{t'}^t (1 + (\mathbb{E}[|Y_0|^{2k}] + K_1(T_s)) K_2(T_s)) \, ds \\
= C_{lgb} 2^{k-1} (1 + (\mathbb{E}[|X_0|^{2k}] + K_1(T_s)) K_2(T_s)) (t-t').
\]

For the second term, we will show
\[
\mathbb{E}[\int_{t'}^t \mathcal{P}_{t}(X_s) b(s, X_s) dW_s |^{2k}] \leq (t-t')^{k-1} [k(2k-1)]^{k} \int_{t'}^t \mathbb{E}[|b(s, X_s)|^{2k}] \, ds.
\]

To see this, let \(I_t := \int_{t'}^t \mathcal{P}_{t}(X_s) b(s, X_s) dW_s\). Then the Itô formula implies
\[
d|I_t|^{2k} = 2k |I_t|^{2k-1} \text{sgn}(I_t) \mathcal{P}_{t}(X_s) b(t, X_t) dW_t + \frac{1}{2} 2k(2k-1) |I_t|^{2k-2} \mathcal{P}_{t}(X_s) b(t, X_t) ^2 dt.
\]

Taking the expectation of both sides, by Hölder’s inequality we get
\[
\mathbb{E}[\int_{t'}^t \mathcal{P}_{t}(X_s) b(s, X_s) dW_s |^{2k}] = \mathbb{E}[|I_t|^{2k}] = 0 + k(2k-1) \int_{t'}^t \mathbb{E}[|I_t|^{2k-2} | \mathcal{P}_{t}(X_s) b(s, X_s) |^2] \, ds \\
\leq k(2k-1) \int_{t'}^t \mathbb{E}[|I_t|^{2k-2}]^{1-\frac{k}{2}} \mathbb{E}[|b(s, X_s)|^{2k}]^{\frac{k}{2}} \, ds
\]

By Lemma 4.2, we have \(\int_{t'}^t \mathbb{E}[|X_s|^{2k}] \, ds = \int_{t'}^t \mathbb{E}[|Y_s|^{2k}] \, ds < \infty\) and, hence, by \(\|AB\|_F \leq \|A\|_2 \|B\|_F\) and (2.3), it holds \(\|\int_{t'}^t \mathcal{P}_{t}(X_s) b(s, X_s) dW_s |^{2k}\| < \infty\). This implies that \(|I_t|^{2k} = |\int_{t'}^t \mathcal{P}_{t}(X_s) b(s, X_s) dW_s |^{2k}\|\) is a submartingale. Therefore, it follows
\[
\mathbb{E}[\int_{t'}^t \mathcal{P}_{t}(X_s) b(s, X_s) dW_s |^{2k}] \leq k(2k-1) \mathbb{E}[|I_t|^{2k}]^{1-\frac{k}{2}} \int_{t'}^t \mathbb{E}[|b(s, X_s)|^{2k}]^{\frac{k}{2}} \, ds.
\]
Therefore, one can extend our DO approximation $X$.

By Assumption 4, Proposition 4.3 holds and (4.10) follows by Jensen’s inequality. Therefore, bounding $\int_0^t \mathbb{E}[|b(t, X_t)|^p] dt$ similarly to (4.9) we obtain

$$
\mathbb{E}[\int_0^t \mathcal{P}_d(X_t, b(s, X_s) dW_s)^{2k}] \leq (t - t')^k \left[2k(2k - 1)k! C_{gb}^{2k} - 1 \left(1 + \mathbb{E}[|X_0|^{2k}] + K_1(T_e) \right) K_2(T_e) \right].
$$
Putting all together, (4.8) follows:

$$
\mathbb{E}[|X_t - X_{t'}|^{2k}] \leq 2^{2k-1}(t - t')^{2k-1} \mathbb{E}\left[\int_{t'}^t |a(s, X_s)|^{2k} ds \right] + 2^{2k-1} \mathbb{E}\left[\int_{t'}^t \mathcal{P}_d(X_s, b(s, X_s) dW_s)^{2k}\right]
$$

Having proved these results concerning boundness of $2k$-moments of the DO solution, we are now ready to extend it up to the explosion time $T_e$ with a.s. continuous paths.

**Theorem 4.4.** Let $a$ and $b$ satisfy Assumptions 1 and 2. Let an DO approximation $X$ on $[0, T_e)$ be given. If $X_0$ satisfies Assumption 4 for some integer $k > 1$, then $X$ admits a unique continuous extension to $[0, T_e]$, almost surely. This extension is Hölder continuous on $[0, T_e]$, and satisfies $\mathbb{E}[|X_t|^{2k}] < \infty$ for all $t \in [0, T_e]$.

**Proof.** By Assumption 4, Proposition 4.3 holds and $(X_t)_{0 \leq t < T_e}$ admits an extension $X_{T_e} := \lim_{t \uparrow T_e} X_t \in L^{2k}(\Omega; \mathbb{R}^d)$ that is unique in $L^{2k}(\Omega; \mathbb{R}^d)$. From $\|X_t - X_{t'}\|_{L^{2k}(\Omega; \mathbb{R}^d)} \leq \|X_t - X_{t'}\|_{L^{2k}(\Omega; \mathbb{R}^d)}$ for $0 \leq t' < t < T_e$, the extension is unique in $L^p(\Omega; \mathbb{R}^d)$ for $p \in [2, 2k]$. By construction of $X_{T_e}$, we have

$$
\mathbb{E}[|X_t - X_{t'}|^{2k}] \leq C(t - t')^k, \quad 0 \leq t' < t < T_e.
$$

Therefore, by Kolmogorov-Chenstov Theorem (see for example [11]) there exists a version $(\tilde{X}_t)_{t \in [0, T_e]}$ of the DO approximation that is $\gamma$-Hölder continuous for all $0 < \gamma < \frac{k - 1}{2k}$. By construction, $(\tilde{X}_t)_{t \in [0, T_e]}$ is a process with bounded $2k$-moments.

Finally, let us see that $(X_t)_{t \in [0, T_e]}$ and $(\tilde{X}_t)_{t \in [0, T_e]}$ are indistinguishable. Indeed, by construction of $\tilde{X}$ we have $X_{T_e} = \tilde{X}_{T_e}$ a.s. Moreover, $(X_t)_{t \in [0, T_e]}$ and $(\tilde{X}_t)_{t \in [0, T_e]}$ have a.s. continuous paths and are versions of each other, and thus indistinguishable. Hence, $(X_t)_{t \in [0, T_e]}$ and $(\tilde{X}_t)_{t \in [0, T_e]}$ are indistinguishable. This completes the proof.

Together with Proposition 4.1, Theorem 4.4 gives us an insight into how to continue a DO approximation beyond the explosion time $T_e$. Let a DO approximation $X$ of (2.1) with explosion time $T_e$ that satisfies (4.5) be given. Suppose $\dim(\text{Im}(\mathbb{E}[X_t])) = R$ for all $t \in [0, T_e)$, with a positive integer $R$. By Theorem 4.4, $X$ can be continuously extended up to $T_e$, while from Proposition 4.1 we know $\lim_{t \uparrow T_e} \left\|C_{\gamma,t}^{(1)} \right\|_{\mathcal{F}} = \infty$. This implies that $\dim(\text{Im}(\mathbb{E}[X_{T_e}])) = R' < R$.

Therefore, one can extend our DO approximation $X$ continuously in $t$ beyond $T_e$ by considering the DO system (2.6)–(2.7) with initial datum $X_{T_e}$. The corresponding DO solution satisfies $U_t \in \mathbb{R}^{R' \times d}$ and $Y_t \in [L^2(\Omega)]^{R'}$ for $t \in [T_e, T_e + T'_e)$, where $T'_e$ is the new explosion time for $(U_t, Y_t)$.
4.3 The case of uniformly positive-definite diffusion

In the previous section, we have shown that by assuming the boundedness of the 2k moments of the initial condition of the DO approximation for $k > 1$, the DO approximation can be extended up to the explosion time $T_e$. It turns out that, under the condition that we will introduce in the following, the explosion time $T_e$ is never finite; as a result, rank-R DO solution exists globally.

A sufficient condition is that the diffusion matrix $b(t, x)b(t, x)^\top$ is positive definite with a lower bound on the smallest eigenvalue, where the bound is uniform in $t$ and $x$. This condition turns out to ensure that the smallest eigenvalue of the Gram matrix $E[Y_t Y_t^\top]$ remains bounded below uniformly in $t$ and $x$, which in turn guarantees the global existence of the DO solution.

In the following, we use the notation $A \succ B$ (respectively $A \succeq B$) with $A, B$ square matrices to indicate that $A - B$ is positive definite (respectively positive semidefinite).

**Proposition 4.5.** Suppose the rank $R$ DO solution $(U, Y)$ exists on $[0, T]$. Assume moreover that there exist $\sigma_{Y_0}, \sigma_B > 0$ such that

\[
C_{Y_0} := E[Y_0 Y_0^\top] \succeq \sigma_{Y_0} I_{R \times R}; \quad b(t, x)b(t, x)^\top \succeq \sigma_B I_{d \times d}, \quad \text{for any } t \in [0, T] \text{ and for any } x \in \mathbb{R}^d.
\]

Then for all $t \in [0, T]$ we have

\[
C_{Y_t} \succeq \min\{\sigma_{Y_0}; \frac{\sigma_B^2}{4\text{deg}(1 + M)}\} I_{R \times R},
\]

where $M = M(T)$ is defined in Lemma 3.5.

**Proof.** By introducing the shorthand notation $a_t = a(t, X_t) \in \mathbb{R}^d$ and $b_t = b(t, X_t) \in \mathbb{R}^{d \times m}$, the $k$-th component $Y_t^k$ of $Y_t \in [L^2(\Omega)]^R$ satisfies

\[
dY_t^k = \sum_{i=1}^d U^{ki}_t a_t^i dt + \sum_{l=1}^m \sum_{r=1}^d U^{kr}_t b_t^l dW_t^l.
\]

Hence, using Itô’s formula for $1 \leq j, k \leq R$, we have

\[
d(Y_t^j Y_t^k) = d(Y_t^j)Y_t^k + Y_t^j d(Y_t^k) + \sum_{l=1}^m \sum_{i=1}^d U^{ji}_t b_t^l dt \sum_{r=1}^d U^{kr}_t b_t^l dt
\]

\[
= (\sum_{i=1}^d U^{ji}_t a_t^i dt + \sum_{i=1}^d \sum_{l=1}^m U^{ji}_t b_t^l dW_t^l)Y_t^k + Y_t^j (\sum_{i=1}^d U^{ki}_t a_t^i dt + \sum_{l=1}^m \sum_{i=1}^d U^{kr}_t b_t^l dW_t^l)
\]

\[
+ \sum_{i=1}^m \sum_{l=1}^d U^{ji}_t b_t^l \sum_{r=1}^d U^{kr}_t b_t^l
\]

Hence,

\[
d(Y_t Y_t^\top) = (dY_t)Y_t^\top + Y_t(dY_t)^\top + U_t b_t (U_t b_t)^\top dt
\]

and taking the expectation of both sides yields

\[
\frac{dE[\{Y_t Y_t^\top\}]}{dt} = E[U_t a_t (Y_t^\top)] + E[Y_t (U_t a_t)^\top] + E[U_t b_t b_t^\top U_t^\top].
\]

We now aim at analyzing the smallest eigenvalue of $C_{Y_t} := E[\{Y_t Y_t^\top\}]$ through the Rayleigh quotient. For any unit vector $v \in \mathbb{R}^R$, we have

\[
v^\top \frac{dE[\{Y_t Y_t^\top\}]}{dt} v = 2v^\top E[U_t a_t (Y_t^\top)] v + v^\top E[U_t b_t b_t^\top U_t^\top] v.
\]

(4.17)
Thanks to (4.15), the last term can be bounded below as
\[ v^\top \mathbb{E}[U_t b_t b_t^\top U_t^\top] v = v^\top U_t \mathbb{E}[b_t b_t^\top] U_t^\top v \geq v^\top U_t \sigma_B I_{R \times R} U_t^\top v \geq \sigma_B. \]

The first term can be bounded above as
\[
|v^\top \mathbb{E}[Y_t (U_t a_t)^\top] v| = |\mathbb{E}[v^\top Y_t a_t U_t^\top v]| \leq \mathbb{E}[|v^\top Y_t a_t^\top|] \\
\leq \frac{1}{2\varepsilon} \mathbb{E}[|v^\top Y_t|^2] + \frac{\varepsilon}{2} \mathbb{E}[|a_t|^2] \\
\leq \frac{1}{2\varepsilon} \mathbb{E}[v^\top Y_t Y_t^\top v] + \frac{\varepsilon}{2} C_{\text{lbs}} (1 + \mathbb{E}[|Y_t|^2]) \\
\leq \frac{1}{2\varepsilon} v^\top \mathbb{E}[Y_t Y_t^\top] v + \frac{\varepsilon}{2} C_{\text{lbs}} (1 + M) \quad \text{for any } \varepsilon > 0.
\]

Taking \( \varepsilon = \frac{\sigma_B}{4C_{\text{lbs}}(1+M)} \) leads to the following estimate on the derivative of \( A_t := v^\top C_Y v = v^\top \mathbb{E}[(Y_t Y_t^\top)] v \):
\[
\frac{d}{dt} A_t \geq -\frac{1}{\varepsilon} A_t + \frac{\sigma_B}{2}, \quad (4.18)
\]
from which we deduce
\[ A_t \geq \frac{\sigma_B}{2} + (\sigma_Y - \frac{\sigma_B}{2}) e^{-\frac{t}{\varepsilon}} + A_0 e^{-\frac{t}{\varepsilon}}. \]

Noting that (4.14) implies \( A_0 \geq \sigma_Y \), we conclude
\[
v^\top \mathbb{E}[Y_t Y_t^\top] v \geq \frac{\sigma_B}{2} + (\sigma_Y - \frac{\sigma_B}{2}) e^{-\frac{t}{\varepsilon}} \\
\geq \min\{\sigma_Y, \frac{\sigma_B^2}{4C_{\text{lbs}}(1 + M)}\} > 0 \quad \text{for any } t \in [0, T].
\]

As a consequence of the proposition above, the following global existence result is obtained.

**Theorem 4.6 (Global Existence of DO solution).** Let Assumptions 1–3 hold. Suppose that the assumptions of Proposition 4.5 hold. Then, the DO solution exists for all \( t \geq 0 \).

**Proof.** From Theorems 3.4 and 3.6, the rank \( R \) solution uniquely exists up to a certain time \( T > 0 \). Denote by \( T_c \) its explosion time and suppose, to obtain a contradiction, \( T_c < +\infty \). Then, from Proposition 4.1 we have \( \lim_{t \uparrow T_c} \|C_Y^{-1}\|_F = +\infty \). But by Proposition 4.5 the Rayleigh quotient \( A_t = v^\top C_Y v \) with \( v \in \mathbb{R}^R \) satisfies
\[ A_t \geq \min\{\sigma_Y, \frac{\sigma_B^2}{4C_{\text{lbs}}(1 + M(T_c))}\} > 0, \]
and, hence, for some constant \( \bar{k} > 0 \) we have \( \|C_Y^{-1}\|_F \leq \bar{k} \) for all \( t \in [0, T_c] \). This contradicts \( \lim_{t \uparrow T_c} \|C_Y^{-1}\|_F = +\infty \). Therefore, \( T_c = +\infty \). \( \square \)

**Remark 4.7.** It is worth noticing that (4.15) is satisfied in the case of additive non-degenerate noise.

## 5 Conclusion

In this work, we achieved to set a rigorous DO setting for SDEs under the conditions that the studied drift and diffusion satisfy a Lipschitz condition and a linear-growth bound. First, we (re-)derived the equations which characterize the evolution of the deterministic and stochastic modes,
in a DO formulation, and showed how these can be re-interpreted as a projected dynamics leading to a DLRA formulation. Our derivation makes use of the Itô’s formula and avoids the direct use of time derivatives. We proved local-existence and uniqueness of the DO formulation and analyzed the possibility of extending the solution up to and beyond the explosion time. Finally, we gave a sufficient condition that assures the global existence of the DLR approximation.

One natural development of this work would be to extend this DO framework and well-posedness results to accommodate weaker assumptions on the drift and diffusion (e.g. local lipschitzianity and/or weak monotonicity).

Furthermore, it would be interesting to build a DLR formulation as a fully projecting dynamics as in (2.18) by giving a rigorous meaning to the term $\mathcal{P}_{\mathcal{Y}(X_{t})}[b(t, X_{t}) dW_{t}]$, possibly in a distributional sense. In case one manages to achieve this goal, the direct connection to the standard DLRA formulation for deterministic or random equations would allow us to apply numerical projector splitting schemes, which have been shown to perform very well in those contexts [5, 23].

A Appendix

For a Hilbert space $(H, \langle \cdot, \cdot \rangle)$, denote by $[H]^R$ the product Hilbert space equipped with the norm $\|Y\|_{[H]^R} = \sqrt{\sum_{j=1}^{R} \|Y_{j}\|_{H}^2}$ for $Y = (Y_{j}) \in [H]^R$. For $Y \in [H]^R$ let $Z_{Y}$ be the Gram matrix

$$Z_{Y} := (\langle Y_{j}, Y_{k} \rangle)_{j,k=1,...,R} \in \mathbb{R}^{R \times R}.$$ 

If $Z_{Y_{0}}$ is invertible, then for $Y$ close to $Y_{0}$, $Z_{Y}$ is also invertible. The following result makes this intuition precise.

**Proposition A.1.** Suppose that $Y_{0} \in [H]^R$ has linearly independent components $Y_{0j}, j = 1, \ldots , R$ in $H$, and that $\|Y_{0}\|_{H} \leq \rho$ and $\|Z_{Y_{0}}^{-1}\|_{F} \leq \gamma$ hold for $\rho, \gamma > 0$. Then, there exists $\eta := \eta(\rho, \gamma) > 0$ such that we have

$$\|Z_{Y}^{-1}\|_{F} \leq 2\gamma,$$

for any $Y \in B_{\eta}(Y_{0})$,

and $\eta(\rho, \gamma)$ is decreasing in both $\rho$ and $\gamma$. Here, $B_{\eta}(Y_{0})$ is the open ball in $[H]^R$ of radius $\eta$ around $Y_{0}$.

**Proof.** Any $Y \in B_{\eta}(Y_{0})$ may be written as $Y = Y_{0} + r\delta$ with $r < \eta$ and $\|\delta\|_{[H]^R} = 1$. We will derive an upper bound $\eta$ on $r$ that guarantees $\|Z_{Y}^{-1}\|_{F} \leq 2\gamma$.

Define $Y(s) := Y_{0} + s\delta$ and let $f(s) := Z_{Y(s)}^{-1}$. Then, we have

$$\frac{d}{ds}f(s) = -f(s) \left( (\delta_{j}, Y(s)^{k}_{j})_{j,k=1,...,R} + (\langle Y(s)^{j}_{j}, \delta^{k}_{j} \rangle)_{j,k=1,...,R} \right) f(s).$$

$$26$$
Therefore, it holds
\[
\frac{d}{ds} \|f(s)\|_F^2 = \frac{d}{ds} \text{Tr}(f(s)^T f(s)) \\
= -\text{Tr}(f(s)(Z_{\delta Y}(s) + Z_Y(s), \delta)f(s)^T) - T_s(f(s)^T(s)(Z_{\delta Y}(s) + Z_{\delta Y}(s))f^T(s)) \\
\leq 2\|Z_{\delta Y}(s) + Z_Y(s), \delta\|_F\|f^T(s)\|_F \\
\leq 2(\|Z_{\delta Y}(s)\|_F + \|Z_Y(s), \delta\|_F)\|f^T(s)\|_F \\
\leq 4(\|\delta\|_H^2\|Y(s), \delta\|_H)\|f(s)\|_F^2 \\
\leq 4(\rho + s)\|f(s)\|_F^2.
\]

Let \(E_s = \|f(s)\|_F^2\) so that \(E_s^{-\frac{3}{2}} \frac{dE_s}{ds} \leq 4(\rho + s)\) and
\[
\int_0^\rho 2 \frac{d(-E_s^{-1/2})}{ds} ds = \int_0^\rho E_s^{-\frac{1}{2}} \frac{dE_s}{ds} ds \leq 4\rho r + 2r^2,
\]
which implies \(-2E_s^{-\frac{1}{2}} + 2E_0^{-\frac{1}{2}} \leq 4\rho r + 2r^2\). Now we use \(E_0 \leq \gamma^2\) to obtain the bound \(\gamma^{-1} - 2\rho r - r^2 \leq E_r^{-\frac{1}{2}}\). For any \(0 < r < -\rho + \sqrt{\rho^2 + \frac{1}{\gamma}}\), we have \(\frac{1}{\gamma} - 2\rho r - r^2 > 0\) and thus this bound yields
\[
\|Z_{\delta Y}^{-1}\|_F \leq \frac{1}{\gamma} - 2\rho r - r^2 = \frac{1}{\gamma} + \rho^2 - (\rho + r)^2.
\]
Then, \(\|Z_{\delta Y}^{-1}\|_F^2 \leq 4\gamma^2\) is guaranteed by the condition \(0 < r \leq -\rho + \sqrt{\rho^2 + \frac{1}{\gamma}}\), which also implies \(\frac{1}{\gamma} - 2\rho r - r^2 > 0\) above. Finally,
\[
\eta(\rho, \gamma) := -\rho + \sqrt{\rho^2 + \frac{1}{\gamma}} \tag{A.1}
\]
is decreasing in \(\rho\) and \(\gamma\):
\[
\frac{\partial \eta}{\partial \rho} = -\frac{\rho}{\sqrt{\rho^2 + \frac{1}{\gamma}}} - 1 < 0, \quad \forall \rho, \gamma > 0;
\]
\[
\frac{\partial \eta}{\partial \gamma} = -\frac{1}{4\gamma^2} \frac{1}{\sqrt{\rho^2 + \frac{1}{\gamma}}} < 0, \quad \forall \rho, \gamma > 0.
\]

Recall that a finite rank functions as in Definition 2.4 admits a representation reminiscent of the singular value decomposition as in (A.2) below; see [14, Lemma 2.1]. For such functions that are close enough, the following Lipschitz bounds hold for the projector-valued mappings. The proof of this statement follows closely [3, Proof of Lemma A.2]; see also [41, Lemmata 4.1 and 4.2] for a finite dimensional version.

**Proposition A.2.** Suppose that \(X, \hat{X} \in L^2(\Omega; H)\) have the following representations
\[
X = \sum_{j=1}^R \sigma_j U_j V_j, \quad \hat{X} = \sum_{j=1}^R \hat{\sigma}_j \hat{U}_j \hat{V}_j, \tag{A.2}
\]
with \(\sigma_j, \hat{\sigma}_j > 0\), and \(U_j, \hat{U}_j \in H, V_j, \hat{V}_j \in L^2(\Omega)\) all orthonormal in their respective Hilbert spaces, for \(j = 1, \ldots, R\). Here, \(\sigma_j\) and \(\hat{\sigma}_j\), \(j = 1, \ldots, R\), are ordered in the descending order. Suppose
further that \(\|X - \hat{X}\|_{L^2(\Omega; H)} < \sigma_R/R\) holds. Then, the projections \(P_U = \sum_{j=1}^R \langle U_j, \cdot \rangle_H U_j\) and \(P_V = \sum_{j=1}^R E[V_j \cdot] V_j\) satisfy
\[
\|P_U - P_U\|_{H \to H} \leq \frac{R}{\sigma_R} \|X - \hat{X}\|_{L^2(\Omega; H)} \quad \text{and} \quad \|P_V - P_V\|_{H \to L^2(\Omega; H)} \leq \frac{R}{\sigma_R} \|X - \hat{X}\|_{L^2(\Omega; H)}.
\]
Moreover, we also have
\[
\|P_U + P_V - P_U P_V - (P_U + P_V - P_U P_V)\|_{L^2(\Omega; H) \to L^2(\Omega; H)} \leq \frac{3R}{\sigma_R} \|X - \hat{X}\|_{L^2(\Omega; H)}.
\]
Proof. For any \(f \in L^2(\Omega; H)\), one has
\[
\|P_V f - P_V P_V f\|_{L^2(\Omega; H)} = \|\langle \text{id} - P_V \rangle P_V f\|_{L^2(\Omega; H)} = \|\langle \text{id} - P_V \rangle \sum_{j=1}^R \frac{1}{\sigma_j} E[V_j f] \langle U_j, X \rangle_H\|_{L^2(\Omega; H)}.
\]
and using \(\langle U_j, X \rangle_H = \sigma_j V_j\) it follows
\[
\|P_V f - P_V P_V f\|_{L^2(\Omega; H)} = \|\langle \text{id} - P_V \rangle \sum_{j=1}^R \frac{1}{\sigma_j} E[V_j f] \langle U_j, X \rangle_H\|_{L^2(\Omega; H)}.
\]
From \((\text{id} - P_V)\hat{X} = 0\), we have
\[
0 = \langle U_j, (\text{id} - P_V) \hat{X} \rangle_H = \langle U_j, \hat{X} \rangle_H = \langle U_j, P_V \hat{X} \rangle_H
\]
but [21, Theorem 8.13] implies
\[
\langle U_j, P_V \hat{X} \rangle_H = \sum_{j=1}^R \langle U_j, E[V_j \hat{X}] \rangle_H V_j
\]
\[
= \sum_{j=1}^R E[\langle U_j, V_j \hat{X} \rangle_H] V_j = \sum_{j=1}^R E[V_j (\langle U_j, \hat{X} \rangle_H \rangle V_j = P_V (\langle U_j, \hat{X} \rangle_H),
\]
and thus \((\text{id} - P_V)(\langle U_j, \hat{X} \rangle_H) = 0\) for \(j = 1, \ldots, R\). Therefore, \(\sigma_j^{-1} E[V_j f] (\text{id} - P_V)(\langle U_j, \hat{X} \rangle_H) = 0\) for \(j = 1, \ldots, R\). Hence, the Cauchy–Schwarz inequality and orthonormality assumptions on \(U_j\) and \(V_j\) imply
\[
\|P_V f - P_V P_V f\|_{L^2(\Omega; H)} = \|\langle \text{id} - P_V \rangle \sum_{j=1}^R \frac{1}{\sigma_j} E[V_j f] (\langle U_j, X - \hat{X} \rangle_H\|_{L^2(\Omega; H)}
\]
\[
\leq \|\langle \text{id} - P_V \rangle\|_{L^2(\Omega; H) \to L^2(\Omega; H)} \sum_{j=1}^R \frac{1}{\sigma_j} \|V_j\|_{L^2(\Omega; H)} \|f\|_{L^2(\Omega; H)} \|U_j\|_H \|X - \hat{X}\|_{L^2(\Omega; H)}
\]
\[
\leq \frac{R}{\sigma_R} \|f\|_{L^2(\Omega; H)} \|X - \hat{X}\|_{L^2(\Omega; H)},
\]
and thus the assumption \(\|X - \hat{X}\|_{L^2(\Omega; H)} < \sigma_R/R\) yields \(\|P_V - P_V P_V\|_{L^2(\Omega; H) \to L^2(\Omega; H)} < 1\).
Hence, following the same argument as in [14, Proof of Lemma 3.4], we invoke [13, Lemma 221] (see also [12, Theorem I.6.34]) to obtain
\[
\|P_V - P_V P_V\|_{L^2(\Omega; H) \to L^2(\Omega; H)} = \|P_V - P_V\|_{L^2(\Omega; H) \to L^2(\Omega; H)}.
\]
Therefore, from (A.5) it follows
\[
\|P_V - P_V\|_{L^2(\Omega; H) \to L^2(\Omega; H)} \leq \frac{R}{\sigma_R} \|X - \hat{X}\|_{L^2(\Omega; H)}.
\]
By similar arguments, we can obtain the analogous bound for the projections $P_U = \sum_{j=1}^R \langle U_j, \cdot \rangle h U_j$ and $P_{U'} = \sum_{j=1}^R \langle U'_j, \cdot \rangle h U'_j$ onto the span of $\{U_j\}_j$ and $\{U'_j\}_j$, respectively:

$$\|P_U - P_{U'}\|_{H \to H} \leq \frac{R}{\sigma_R} \|X - \hat{X}\|_{L^2(\Omega,H)}.$$  

Finally, to show (A.4), notice $\|P_U - P_{U'}\|_{H \to H} = \|P_U - P_{U'}\|_{L^2(\Omega,H) \to L^2(\Omega,H)}$.

Then it follows that

$$\|P_U + P_V - (P_U + P_V)\|_{L^2(\Omega,H) \to L^2(\Omega,H)}$$

$$\|P_U - P_{U'}\|_{L^2(\Omega,H) \to L^2(\Omega,H)}$$

$$\|P_U - P_{U'}\|_{L^2(\Omega,H) \to L^2(\Omega,H)}$$

(A.6)

$$\|P_U - P_{U'}\|_{L^2(\Omega,H) \to L^2(\Omega,H)}$$

Then it follows that

$$\|P_U + P_V - (P_U + P_V)\|_{L^2(\Omega,H) \to L^2(\Omega,H)}$$

$$\|P_U - P_{U'}\|_{L^2(\Omega,H) \to L^2(\Omega,H)}$$

$$\|P_U - P_{U'}\|_{L^2(\Omega,H) \to L^2(\Omega,H)}$$

We conclude this section giving another useful result inherent to orthogonal projections.

**Lemma A.3.** Given $\gamma, R > 0$ two positive constants, let

$$B_{\gamma,R} := \{t \in [0,T] \to U_t \in \mathbb{R}^{R \times d} \mid \sup_{s \in [0,T]} \|U_t^{-1} v\|_{F} \leq \gamma \text{ and } \sup_{s \in [0,T]} \|U_t\|_{F} < \sqrt{R}\},$$

where the invertibility of $U_t U_t^\top$ is implicitly assumed. Define the orthogonal projectors $P_{U_t}^{\text{row}} := U_t^\top (U_t U_t^\top)^{-1} U_t$, $P_{U_t}^{\text{row}} := \hat{U}_t^\top (\hat{U}_t \hat{U}_t^\top)^{-1} \hat{U}_t$ onto the rows of $U_t$ and $U'_t$, respectively. Then there exists a constant $C_1 > 0$ such that the following holds

$$\sup_{t \in [0,T]} \|P_{U_t}^{\text{row}} - P_{U_t}^{\text{row}}\|_{F} \leq C_1 \sup_{t \in [0,T]} \|U_t - \hat{U}_t\|_{F}.$$  

Further given $\tilde{\gamma}, M > 0$ two positive constants, let

$$B_{\tilde{\gamma},M} := \{t \in [0,T] \to Y_t \in [L^2(\Omega)]^R \mid \sup_{s \in [0,T]} \|E[Y_t^2]\|_{F} \leq \tilde{\gamma} \text{ and } E\sup_{s \in [0,T]} \|Y_t\|_{2} < M\}.$$  

Given $Y, \tilde{Y} \in B_{\gamma,M}$, let $P_{Y_t}[:]= Y_t^\top E[Y_t Y_t^\top]^{-1} E[Y_t]$, $P_{\tilde{Y}_t}[:]= \tilde{Y}_t^\top E[\tilde{Y}_t \tilde{Y}_t^\top]^{-1} E[\tilde{Y}_t]$ be the orthogonal projectors onto the subspaces spanned by the components of $Y_t$ and $\tilde{Y}_t$, respectively. Then there exists a constant $C_2 > 0$ such that the following holds

$$E\sup_{t \in [0,T]} \|P_{Y_t} - P_{\tilde{Y}_t}\|_{L^2(\Omega) \to L^2(\Omega)}^2 \leq C_2 E\sup_{t \in [0,T]} \|Y_t - \tilde{Y}_t\|_{2}^2.$$  

**Proof.** For $Y_t, \tilde{Y}_t \in [L^2(\Omega)]^R$ we have

$$Y_t^\top E[Y_t Y_t^\top]^{-1} E[Y_t g] - \tilde{Y}_t^\top E[\hat{Y}_t \hat{Y}_t^\top]^{-1} E[\hat{Y}_t g]$$

$$= (Y_t^\top - \hat{Y}_t^\top) E[Y_t Y_t^\top]^{-1} E[Y_t g]$$

$$+ \hat{Y}_t^\top (E[Y_t Y_t^\top]^{-1} - E[\hat{Y}_t \hat{Y}_t^\top]^{-1}) E[Y_t g]$$

$$+ \hat{Y}_t^\top E[\hat{Y}_t \hat{Y}_t^\top]^{-1} (E[Y_t g] - E[\hat{Y}_t g]).$$
Let $Y, \tilde{Y} \in B_{r,M}$. From [14, Lemma 3.5], there exists a constant $C(R,M) > 0$ such that

$$\|E[Y_t Y_t^\top]^{-1} - E[\tilde{Y}_t \tilde{Y}_t^\top]^{-1}\|_F \leq \tilde{C}(R,M)E[\sup_{t \in [0,T]} |Y_t - \tilde{Y}_t|^2]^{1/2},$$

and thus

$$\sup_{t \in [0,T]} |(P_{Y_t} - P_{\tilde{Y}_t})g| \leq \tilde{C}(R,M)\left(\sup_{t \in [0,T]} |Y_t - \tilde{Y}_t| \left(E[\sup_{t \in [0,T]} |Y_t||g|]\right)\right) + \left(\sup_{t \in [0,T]} |\tilde{Y}_t|\right)\tilde{C}(R,M)\left(E[\sup_{t \in [0,T]} |Y_t - \tilde{Y}_t||g|]\right).$$

Then, using the Cauchy–Schwarz inequality to $E[\sup_{t \in [0,T]} |Y_t||g|]$ and $E[\sup_{t \in [0,T]} |Y_t - \tilde{Y}_t||g|]$, taking the square of both sides and taking the expectation yields the result. The result for $P_{U_t}$ can be analogously shown. \[\square\]
